CHAPTER 1 **Documentation & Support**

UAD Documentation Overview

Mac

This section describes the various instructional and technical resources that are available for installing, using, and troubleshooting UAD Powered Plug-Ins. Documentation for the product line is available in written, video, and online formats. Note: Unless specified otherwise, for descriptive purposes within this manual, "UAD-2" means all UAD-2 family products (SOLO, DUO, QUAD, OCTO, UAD-2 Satellite, and Apollo audio interfaces). ReadMe The ReadMe contains information that may not be available in other locations. Please review all the information in the ReadMe before installing or using UAD Powered Plug-Ins. The ReadMe.rtf file is presented for viewing during the software installation process, and installed to: Windows Start Menu>All Programs>UAD Powered Plug-Ins /Applications/Universal Audio Operation Documentation for UAD-2 and UAD Powered Plug-Ins are separated by areas Manuals of functionality, as described below. The user manuals are placed in the Documentation folder during software installation. All manuals are in PDF format. PDF files require a free PDF reader application such as Adobe Reader (Windows) or Preview (Mac).

UAD System Manual

The UAD System Manual is the complete operation manual for UAD functionality and applies to the entire UAD product line. It contains detailed information about installing and configuring UAD devices, the UAD Meter & Control Panel application, how to use UAD Powered Plug-Ins within a DAW, obtaining optional plug-in licenses at the UA online store, and more. It includes everything about UAD except Apollo-specific information and individual UAD Powered Plug-In descriptions.

UAD Plug-Ins Manual

The features and functionality of all the individual UAD Powered Plug-Ins is detailed in the UAD Plug-Ins Manual. Refer to this document to learn about the operation, controls, and user interface of each individual UAD plug-in.

Direct Developers

UAD Powered Plug-Ins includes plug-ins from our Direct Developer partners. Documentation for these 3rd-party plug-ins are separate files that are written and provided by the plug-in developers themselves. The filenames for these plug-ins are the same as the plug-in names.

Apollo Software Manual

The Apollo Software Manual contains detailed information about how to configure and control Apollo's software features using the Console application and Console Recall plug-in. Refer to the Apollo Software Manual to learn how to operate these software tools and integrate Apollo's audio interface functionality into the DAW environment.

Apollo Hardware Manuals

The Apollo Hardware Manual, Apollo Twin Hardware Manual, and Apollo 16 Hardware Manual (all available separately) contain complete information about the audio interface hardware. Included are detailed descriptions for all Apollo hardware features, control functions, and connections. Refer to the Apollo Hardware Manuals to learn all about interfacing the hardware with other devices, operating the panel controls, clocking, specifications, and related information.

Installed Locations

The UAD and Direct Developer manual files are copied to the hard drive by the software installer to the following locations:

- Start Menu>All Programs>UAD Powered Plug-Ins>Documentation
- Mac

Windows

• /Applications/Universal Audio/

Online Documentation	The technical support pages on our website offer a wealth of helpful informa- tion that is not included in the documentation contained within the software bundle. Please visit our support pages for important technical information in- cluding the latest release notes, host application notes, and more. The main UAD Powered Plug-Ins support page is:
Support Website	• www.uaudio.com/support
Videos	The Universal Audio website contains many helpful videos that explain how to install UAD hardware and software, register and authorize the products, obtain optional plug-ins, and more:
	• www.uaudio.com/videos
Blog	Universal Audio's online magazine is published regularly and contains lots of useful and interesting information. How-to pages, artist/producer/engineer interviews, support Q & A, detailed scientific notes, and other fascinating articles make the UA blog a great place to routinely visit:
	• www.uaudio.com/blog
Users Forum	The unofficial UAD Powered Plug-Ins users forum, for the exchange of tips and information, is on the world wide web at:
	• www.uadforum.com

Customer Support

Customer support is provided by Universal Audio staff to all registered UAD Powered Plug-Ins users.

- **Support Hours** Support specialists are available to assist you via email and telephone during our normal business hours, which are from 9am to 5pm, Monday through Friday, Pacific Standard Time.
- Phone Support Customer Service & Technical Support USA toll-free: +1-877-698-2834 International: +1-831-440-1176

Online Support To request online support, please visit the UA support pages, then click the blue "Submit Support Ticket" button to create a help ticket:

- www.uaudio.com/support
- Website www.uaudio.com
- Address Universal Audio, Inc. 4585 Scotts Valley Drive Scotts Valley, CA 95066-4517 USA
- Feedback Your feedback on the performance and features of UAD Powered Plug-Ins is very important to us. Please send your comments and suggestions to us. Comments (not technical support issues) may be sent to info@uaudio.com.

Ampex ATR-102

Mastering Tape Recorder

It's Not a Record Until it's Mastered on an Ampex® Tape Machine.

For more than three decades, the two-channel Ampex ATR-102 Mastering Tape Recorder has turned music recordings into records. With its cohesive sound, punch, and ability to provide subtle-to-deep tape saturation and color, the Ampex ATR-102 is a fixture in major recording and mastering studios and is considered by many engineers to be the best-sounding tape machine for final mixdown. The perfect complement to the workhorse Studer 800 Multichannel Tape Recorder, the Ampex ATR-102 plug-in can provide the final "analog polish" on your music, turning songs into albums.

Impeccably modeled in the renowned UAD engineering tradition — and incorporating presets from noted Ampex ATR-102 users Chuck Ainlay, Richard Dodd, Buddy Miller, Mike Poole, and more — the Ampex ATR-102 Mastering Tape Recorder plug-in emulation for UAD-2 faithfully replicates the unique dynamics, frequency response, and saturation characteristics of the original hardware. Scrutinized and fully authenticated by the Ampex Corporation, the sound of the Ampex ATR-102 plug-in for UAD-2 is virtually indistinguishable from its analog cousin.

History Introduced in 1976, the Ampex ATR-102 2-Track Tape Recorder was a near-instant hit, thanks to its revolutionary servo-controlled reel motors and capstan, which provided smooth, continuous tape tension and handling. The large capstan, and absence of pinch rollers, provided nearly non-existent speed drift and ultra-low flutter. The clever ATR-102 design allowed users to change out heads and guides in mere minutes, with a 1" head being a very popular "hot-rod" modification in more recent years — especially when running at 15 IPS (inches per second). The ATR's role in modern recording history is so prevalent, that it would be easier to list classic albums that weren't mixed down on this machine, rather than to try to list all those that were.

All visual and aural references to the Ampex Product and all use of Ampex's trademarks are being made with written permission from Ampex Corporation. Any references to third party tape formulations are used solely for identification and do not imply any endorsement by, or affiliation with, any tape manufacturer.

Ampex ATR-102 Screenshots

Figure 2. Ampex ATR-102 secondary controls in "open" mode

Operational Overview

Famous Tape Sound	The UAD Ampex ATR-102 provides all of the original unit's desirable analog sweetness. Like magnetic tape, users can dial in a clean sound, or just the right amount of harmonic saturation.
Mixdown Tape Deck	The primary purpose of the UAD Ampex ATR-102 is to obtain tape mixdown sonics within the DAW environment. To obtain the classic tape mixdown sound, instantiate the plug-in as the last insert on the output bus, after other processing is applied (or possibly as the second-to-last insert, before a brick-wall processor such as the (UAD Precision Limiter). Of course, creative "non-standard" results can be obtained by placing the Ampex ATR-102 in any channel insert or on busses in a send/return configuration.
Multiple Tape Types	The UAD Ampex ATR-102 models seven popular magnetic tape formulas. Each type has its own subtle sonic variation, distortion onset, and tape com- pression characteristics. The tape types that can be selected depend on the active tape speed and head type; all tape types are not available for all tape speeds and head types. Lower fidelity types are included to facilitate more signal coloration options.
Multiple Tape Heads	The original hardware machine was manufactured with an interchangeable head block system which enabled the system to be quickly converted to use either 1/4" or 1/2" tape stock by simply swapping out the heads and recalibrating the electronics. As track width increases, subtle improvements to stability, fidelity, and noise become apparent. A popular custom aftermarket tape head is available which enables the use of 1" tape stock, enabling even higher fidelity with its greater track widths. All three tape head widths are accurately modeled and selectable in the UAD Ampex ATR-102.
Multiple Tape Speeds	All four tape speeds in the original hardware are modeled in the UAD Ampex ATR-102. Speeds of 3.75, 7.5, 15, and 30 inches per second (IPS) are available. Each speed provides distinct frequency shift, head bump, and distortion characteristics. Higher speeds have higher fidelity; 3.75 IPS has a distinct tively "lo fi" character.
Multiple Calibration Levels	Tape machines can be setup with different calibration levels, which entails set- ting unity gain from input through output based on the magnetic flux (amount of magnetic field) of a given tape formulation. Different calibration levels pro- vide different tape response characteristics for a given level into the recorder. Four selectable calibration levels are available in the UAD Ampex ATR-102.

Ancillary Noises	Tape recorders have inherent signal noises that are a by-product of the elec- tro-mechanical nature of the machine. While "undesirable" tape system noise is historically considered a negative and was an attribute that pushed the technical envelope for better machine design and tape formulas (and ulti- mately, "noiseless" digital recorders), noise is still an ever-present character- istic of the sound of using tape and tape machines.
	The UAD Ampex ATR-102 models the hum, hiss, wow, flutter, and crosstalk characteristics of the original hardware. These noise components can be in- dividually disabled, adjusted, and/or exaggerated for creative purposes (even though the servo-controlled, direct-drive capstan tape transport of the original hardware provides excellent wow and flutter specifications).
Modeled Transformer	The original hardware was manufactured with isolation transformers, which can color the signal. A common modification to the hardware tape machine eliminates the transformers from the signal path to produce a (subjectively) "cleaner" sound. UAD Ampex ATR-102 simulates the behavior of the trans- formers in the hardware circuit, and can be optionally disabled in the plug-in, providing both sonic options.
Tape Delay	A popular application of multi-head tape recorders is to employ them for slap- back tape echo effects. If the machine is running in record mode but the re- corded signal is monitored from the repro head (as opposed to the sync head), the physical space between these two heads results in a short delay be- tween the signal sent to the recorder and the monitored signal. When these signals are combined with mixer routings, the classic slapback echo is mani- fest. The UAD Ampex ATR-102 implements the ability to reproduce this classic effect with a simple set of controls, and expands the capabilities by extending the available delay times beyond what is possible in the physical realm.
Automatic Calibration	The ability of a magnetic tape recorder, which has inherently non-linear re- sponse characteristics, to accurately reproduce an audio signal with a mini- mum of noise and distortion requires precise adjustments to the system elec- tronics. The calibration settings are based on the current tape speed, formulation, emphasis EQ, and tape width. The hardware must be meticu- lously re-adjusted each time a different tape, speed, emphasis EQ, or head width is used (and for system wear and drift, even if these variables are not changed). UAD Ampex ATR-102 has an automatic calibration feature that tunes all calibration electronics with a single button.

Low Level Tuning	Even though automatic calibration is available, the individual controls that ad- just calibration are exposed for sonic manipulation. Playback EQ, record (tape) EQ, and record bias can easily be altered for manual calibration and/or creative purposes.
Manual Calibration Tools	UAD Ampex ATR-102 includes the full suite of tools required to manually cal- ibrate the recorder. Manual calibration tools are provided so expert users can calibrate the system to their preferred methods for obtaining desired results. The manual calibration tools consist of a tone generator (with multiple test tones and levels), a distortion meter with digital readouts, and a full suite of Magnetic Reference Laboratory (MRL) alignment tapes, which are used to cal- ibrate playback electronics.
Mono/Stereo Operation	While the UAD Ampex ATR-102 is a true stereo processor designed primarily for use in stereo-in/stereo-out configurations, it will also operate in mono-in/stereo-out and mono-in/mono-out modes.
	When used in a mono-in/stereo-out configuration, the mono input signal is sent to both channels of the processor, which can then be adjusted indepen- dently. When used in a mono-in/mono-out configuration, adjusting any left or right control will change both the left and right controls (the left/right controls are always linked in mono mode).
Quick Setup	Set up the plug-in by first adjusting Tape Speed, Tape Type (tape formulation), and Emphasis EQ, or simply select a factory preset. Note that as you lower the tape speed, the tape "sound" becomes more audible. Once this basic setup is made, adjust the L/R Record (gain) levels, for more or less tape/circuit coloration/saturation.
Artist Presets	UAD Ampex ATR-102 includes artist presets from prominent ATR-102 users. Some of the artist presets are in the internal factory bank and are accessed via the host application's preset menu. Additional artist presets are copied to disk by the UAD installer. The additional presets can be loaded using the Set- tings menu in the UAD Toolbar.
Primary & Secondary Controls	The graphical interface panel has two modes; open and closed. In closed mode, the primary controls (those that are typically most used) are available on the main panel interface and the tape reels are visible. Additional (typically less used) controls are available on the secondary panel in open mode. The secondary controls panel (Figure 4 on page 32) is accessed by clicking the OPEN button beneath the AMPEX label.

Primary Controls

Meters The two Meters display signal levels of the plug-in for the left and right channels. Meter ballistics of the original hardware are modeled. The Meters can be switched to display input or output levels in peak or VU modes.

Figure 3. One side of the Ampex ATR-102 "penthouse" showing meter and I/O controls

The plug-in operates at an internal level of -12 dBFS. Therefore a digital signal with a level of -12 dB below full scale digital (0 dBFS) at the plug-in input will equate to 0 dB on the Meters when Reproduce is in its calibrated position, which is marked with the "red arrow sticker."

When Path Select is set to Thru, the Meters indicate signal levels at the input of the plug-in prior to processing.

Note: Although there are separate left/right Meter controls for VU/Peak and Input/Output, these controls are permanently linked and cannot be switched individually for the left and right channels.

Input/Output These switches change the Meter to display levels at the input or output of the plug-in. Input metering is a UAD-only feature which is unavailable in the original hardware.

Input

When in Input mode, the Meter reflects the signal level after the Record (input) gain when Path Select is set to Sync or Repro. In Input mode when Path Select is set to Thru, the Meter reflects the pre-processed (raw input) signal level.

Output

When in Output mode, the meter reflects the signal level at the output of the plug-in, which is just after the Reproduce (output) gain.

Peak/VU This switch is used to change Meter behavior between Peak or VU modes.

Clip LED The left and right channels each have a Clip LED, just above the Meter. The Clip LED is not in the original hardware; it is a UAD-only feature.

The Clip LED illuminates only when the machine's audio electronics clip. The Clip LED is not affected by the recorded tape signal, even if the tape is overloaded and distorting.

Reproduce

Reproduce adjusts the signal level coming off the virtual tape before the signal is sent to the Meters. There are two Reproduce controls, one each for the left and right channels. The left/right Reproduce controls can be adjusted individually, or simultaneously adjusted when Link mode (page 26) is active.

The available range is $-\infty$ dB (off) to +9.48 dB. The default value of 0 dB is the "calibrated position" which is marked with a "red arrow sticker." Reproduce is not affected by Auto Cal.

Tip: Click the "REPRODUCE" label text to return Reproduce to 0 dB.

The Meters accurately reflect the output level (when set to Output mode) even if Reproduce is not in its calibrated position. However, if Reproduce is moved from the "cal" position, the Meters will no longer correspond to a particular level being recorded onto the virtual tape. In this case, the Meters will not reflect the actual "operating level" of the tape because Reproduce changes the signal level coming off the tape before it is sent to the Meters.

Note: The graphical interface panel values for Reproduce, which range from 0 – 10, are arbitrary and do not reflect a particular dB value.

Record

Record adjusts the signal level into the plug-in and the tape circuitry. There are two Record controls, one for the left channel and one for the right. These left/right Record controls can be adjusted individually, or simultaneously when Link mode (page 26) is active.

The available range is $-\infty$ dB (off) to +9.3 dB. The default value is 0 dB. The graphical interface panel values, which range from 0 – 10, are arbitrary and do not reflect a particular dB value.

Tip: Click the "RECORD" label text to return the Record value to 0 dB.

Record is a primary "color" control for the plug-in. Just like genuine magnetic tape, lower Record levels will have a cleaner sound, while higher levels result in more harmonic saturation and coloration. Higher Record levels will also increase the output level from the plug-in. The Reproduce control can be lowered to compensate if unity gain operation is desired.

Reproduce/Record Controls Arrangement

Note that the Reproduce control is to the left of the Record control, which is atypical of most signal flow designs, where inputs usually precede outputs (flowing from left to right). This quirky arrangement of the Ampex ATR-102 I/O controls, where the input control "follows" the output control, is true to the original hardware design. In Controls View, the Record (input) control precedes the Reproduce (output) control.

Open/Close The secondary controls (Figure 4 on page 32) are accessed by clicking the OPEN button beneath the AMPEX label. Conversely, the panel is closed by clicking the CLOSE button.

Link/Unlink

Link mode is a software-only addition that enables controls that are identical for the left and right channels to be linked for ease of operation when both channels require the same values, or unlinked when independent left/right control is desired. In other

The Link parameter is stored within presets and can be accessed via automation.

words, left/right channel controls are ganged together in link mode.

Note: Although there are separate left/right Meter controls for VU/Peak and Input/Output, these controls are permanently linked and cannot be switched individually for the left and right channels, even if Unlink mode is active.

Link

In Link mode, modifying any left or right channel control causes its adjacent stereo counterpart control to snap to the same position.

Important: When Unlink mode is active and Link is enabled, the left channel control values are copied to the right channel. Control offsets between channels are lost in this case.

When Link is active, automation data is written and read for the left channel only. In this case, the automation data for the left will control both channels. Additionally, changing the right channel parameters from a control surface or when in "controls only" (non-GUI) mode will have no effect.

Unlink

When Unlink is active, the controls for the left and right channels are independent. When unlinked, automation data is written and read by each channel separately.

Emphasis EQ The Emphasis EQ buttons determine the active Emphasis EQ values and the frequency of the Hum noise. NAB or CCIR curves can be selected when the Tape Speed is 7.5 or 15 IPS. When the Tape Speed is 30 IPS, neither value is available (the LEDs are dimmed) because the EQ is fixed with the

AES emphasis curve, per the original hardware. At 3.75 IPS, only NAB is available (as it is with the hardware).

When the value is set to NAB (traditionally the United States standard), the Hum Noise frequency is 60 Hz. When set to CCIR (traditionally the standard in Europe and other regions), the Hum Noise frequency is 50 Hz. See "Noise Enable" on page 34 and "Hum" on page 34 for more information about Hum.

Tape Speed and Emphasis EQ were originally practical controls for recording duration versus noise and local standards. Historically, the origin of the tape machine (US or European) dictated the built-in EQ emphasis, but later machines like the Ampex ATR-102 had both circuits available.

CCIR (also known as IEC1) is the EQ pre-emphasis made famous on British records and is considered the technically superior EQ; many say this EQ was part of the "British sound" during tape's heyday. NAB (also known as IEC2) was the American standard with its own sound. AES is truly standardized at 30 IPS and is the sole EQ found on the Ampex ATR-102 at 30 IPS.

Power

Power is the plug-in bypass control. When set to OFF, emulation processing is disabled, the Meters and control LEDs are dimmed, the Bypass LED illuminates, and DSP usage is

reduced. Power is useful for comparing the processed settings to the original signal.

OFF is similar to the Thru position in the Path Select control (page 30) except that the Meters are still active when the Thru control is used. However, in this state, the Meters indicate signal levels at the input of the plug-in prior to processing.

Note: DSP usage is reduced only when DSP LoadLock is disabled. If DSP LoadLock is enabled (the default setting), activating OFF will not reduce DSP usage.

Tape SpeedThe Tape Speed control determines the speed of the tape transport, in inches per second (IPS). Tape Speed affects the recorder's fidelity and associated "head bump" sonics. Head bump is bass frequency build-up that occurs with magnetic tape; the dominant frequencies shift according to transport speed.

To change the Tape Speed value, click the IPS text values, or drag the knob, or click the knob then use the mouse scroll wheel.

15 IPS is considered the favorite for rock and acoustic music due to its low frequency "head bump" (low frequency rise) and warmer sound, while 30 IPS is the norm for classical and jazz due to its lower noise floor, greater fidelity and flatter response. 7.5 and 3.75 IPS are also available for an even more colored experience, with even greater frequency shift and other artifacts.

Note: The available parameter ranges of Tape Type, Head Width, and Emphasis EQ are affected by Tape Speed. See Table 6 on page 44 for details.

Tape Type

Tape Type selects the active tape stock formulation. Seven Tape Types are modeled in the UAD Ampex ATR-102. To select the Tape Type, click the TAPE button to cycle through the available types, or click directly on the Tape Type value label. The active Tape Type is highlighted in yellow.

Note: The available Tape Types and defaults are dependent on the current Tape Speed and Head values. The available Tape Types, and the associated Tape Speed and Head values, are shown in Table 6 on page 44.

Each type has its own subtle sonic variation, distortion onset, and tape compression characteristics. Generally speaking, the lower the Cal Level for each formula, the higher the signal level required to reach saturation and distortion. **Cal Level** Cal Level automatically sets tape calibration/fluxivity. The Cal Level setting takes care of the setup one would need to make under equivalent hardware operation, and sets the reference tape/flux level without disturbing the (unity) gain of the plug-in.

To select the Cal Level, click the CAL button to cycle through the available levels, or click directly on the calibration value label. The active Cal Level is highlighted in yellow. The default value is +6 dB.

Because Cal Level affects the operating levels in the plug-in, it can be used to compensate for overly high (or low) levels at the input of the plug-in. For example, if the input is too hot, lowering the Cal Level will reduce the signal level without changing Record, which can affect the tape saturation characteristics.

Note: The noise floor is affected by the Cal Level when Noise Enable (page 34) is active.

As tape formulas advanced, their output level increased, thus lowering relative noise floor. Under normal use, the machine would be calibrated to the tape's output level. However, sometimes the machine is under-calibrated to leave more headroom for a broader sweet spot or to prevent electronics from clipping. Therefore, one can "go traditional" and calibrate to the recommended levels (Table 1), or select a non-corresponding calibration setting.

As an example, if 456 is the selected Tape Type and when Cal is set at +6 (6 dB higher than the NAB tape standard), the reference flux level is 355 nWb/m (nanoweber per meter) and is 10 dB below the point where THD reaches 3% (referred to as the maximum operating level). Therefore, with a 1 kHz test tone at -12 dBFS sent to the plug-in, with Tape Type set to 456, Cal set to +6, and Auto Cal enabled, output levels of the plug-in will match the input level and fluxivity on the tape will be 355 nWb/m.

The tape manufacturer's recommended calibration settings for each Tape Type are shown in Table 1.

Таре Туре	Calibration	Flux Level
111	+0 dB	177 nWb/m
35-90	+3 dB	251 nWb/m
250	+3 dB	251 nWb/m

Table 1. Tape Manufacturer's Recommended Calibration Levels

Table 1. Tape Manufacturer's Recommended Calibration Levels

456	+6 dB	355 nWb/m
468	+6 dB	355 nWb/m
900	+9 dB	502 nWb/m
GP9	+9 dB	502 nWb/m

Tip: The UAD Ampex ATR-102 default presets bank offers a variety of preset Tape Type, Tape Speed, CAL level, and EQ configurations that are commonly used for the recording of specific genres.

Head Width

This control specifies the active tape head model. Head Widths of 1/4," 1/2," or 1" can be selected.

To select the Head Width, click the HEAD button to cycle through the available values, or click directly on the value label. The active Head Width is highlighted in yellow.

Note: At tape speeds of 3.75" and 7.5" only the 1/4" head can be HEAD used. At these speeds, the 1/2'' and 1'' heads cannot be selected.

Path Select The Path Select buttons specify which of the four possible signal paths is active in the Ampex ATR-102. The active mode is indicated by an illuminated LED above its associated button. The default value is Repro.

Sync

Sync mode models the sound of direct tape recording and playback via the sync/record head, plus all corresponding machine electronics.

Sync mode is generally not used for playback due to its poorer frequency response, but it is included for authenticity and creative purposes.

Repro

Repro mode models the sound of tape recording through the record head and playback through the reproduction head, plus all corresponding machine electronics.

Input

Input mode emulates the sound of the Ampex ATR-102 through the machine electronics only, without tape sonics. This is the scenario when the machine is in live monitoring mode but the tape transport is not running.

Thru

Thru is a processor bypass control. When Thru is enabled, all controls are inactive, emulation processing is disabled, and DSP usage is reduced.

Thru behavior is similar to that of the OFF position in the POWER control (page 27), except that the Meters are still active in Thru mode. In this state, the Meters indicate signal levels at the input of the plug-in prior to processing.

Note: DSP usage is reduced only when DSP LoadLock is disabled. If DSP LoadLock is enabled (the default setting), activating Thru will not reduce DSP usage.

Tape Reels
AnimationWhen the secondary controls panel is closed
(Figure 1 on page 20), by default the graphi-
cal tape reels "spin" if the DAW transport is
running. The tape reels animation can be dis-
abled by clicking the capstan graphic.

Re-clicking the capstan will re-start the animation.

The "spin state" is saved until it is changed again.

Note: Spinning reels automation is not supported in all hosts. In Sonar, the plug-in must be configured as a "tempo-based effect" for reels animation.

Secondary Controls

The secondary controls (Figure 4 below) adjust the various calibration, ancillary noise, tone generator, and tape delay parameters. The secondary controls panel is accessed by clicking the OPEN button beneath the AMPEX label.

Figure 4. UAD Ampex ATR-102 secondary controls

Auto Cal

The Ampex ATR-102 has individual calibration controls for adjusting sync (record) EQ, reproduction (playback) EQ, and record bias, which are used to compensate for the inherent non-linearities of tape systems. On the hardware, these controls

are typically adjusted to calibrate the system for optimum response compensation due to tape non-linearities whenever the tape type, tape speed, emphasis EQ, or head width are changed.

When the Auto Cal (Automatic Calibration) ON button is clicked, the calibration EQ and bias controls are automatically adjusted to their "flat" calibrated position for the currently active Tape Type, Tape Speed, Emphasis EQ, and Head Type. The Auto Cal ON LED illuminates green when the calibration parameters (Shelf EQ, HF EQ, Repro HF, Repro LF, and Bias) are in their calibrated position.

Auto Cal is enabled by default. When Auto Cal is ON, the calibration parameters (Shelf EQ, HF EQ, Repro HF, Repro LF, and Bias) change values whenever Tape Type, Tape Speed, Emphasis EQ, or Head Type is modified. When Auto Cal is OFF, the calibration parameters do not change values when Tape Type, Tape Speed, Emphasis EQ, or Head Type is modified.

Important: Any calibration settings made manually are lost when Auto Cal is activated. Consider saving manual settings as a preset before activating Auto Cal.

After Auto Calibration occurs, the automatically adjusted parameters can be modified to any other value if desired. If a calibration parameter is adjusted while Auto Cal is ON, the ON LED illuminates in red instead of green, indicating that the sys-

tem is no longer in the calibrated state. If the moved controls are subsequently returned to their original position, the LED will return to its green state, indicating the unit is back in calibration.

Tip: To return any of the individual calibration controls to their "flat" (calibrated) position, click the label text adjacent to the control (or, simply re-click Auto Cal to return all calibration controls to their "flat" position).

The "Manual Calibration Procedure" on page 40 has instructions for performing system calibration manually.

Record EQ The Record EQ controls (HF EQ and Shelf EQ) are applied in the tape recording circuit and affect tape saturation characteristics. They compensate for common residual HF loss due to bias optimization and system filtering, and affect HF content in the signal prior to the tape non-linearity.

HF EQ

HF EQ provides high frequency emphasis in the signal recorded to tape.

Shelf EQ

Shelf EQ is another control (in addition to HF EQ) provided to compensate for tape non-linearity. Although adjustment of this control is not part of the Ampex factory calibration procedure, it can be used for customized manual calibrations or creative purposes.

Repro EQ The Repro EQ controls (Repro HF and Repro LF) are post-head controls for tape playback calibration. They affect the signal coming out of the tape circuitry in both Repro and Sync modes.

The Repro EQs are used as filters to shape the frequency response of the system in maintaining a flat response and enable compensation for any tape frequency loss or head wear.

Repro HF

Adjusts the tape playback high frequency content when Path Select is set to Sync or Repro.

Repro LF

Adjusts the tape playback low frequency content when Path Select is set to Sync or Repro.

Bias This control adjusts the amount of bias in the record signal. Bias is defined as an oscillator beyond the audible range ap-

plied to the audio at the record head, allowing for adjustment

of the record behavior. Ideal bias voltage settings provide maximum record sensitivity and low distortion. Intentionally overbiasing is a common technique especially for "tape compression" which produces a warmer, gently saturated sound. Underbiasing can also be used to add distortion and other nonlinear responses, similar to gate chatter or cold solder joints; extremely low voltages may even cause audio to drop out entirely.

Bias voltage, HF/Shelf EQ, and Emphasis EQ (CCIR, NAB, AES) all work together to provide a linear response to the recorded signal. The "flat" (calibrated position) is determined by tape speed, tape type, emphasis EQ, and head width.

Noise Enable

This is a global enable control for the Hum and Hiss effect. When Noise is ON, the level of Hum and Hiss can be independently adjusted using the Hum and Hiss Level controls.

The default values of 0 dB for Hum and Hiss are the actual modeled level in the original hardware. Noise is not affected by automatic calibration.

Hum Determines the amount of Hum in the signal. Hum is added after the tape circuitry. This control affects both the left and right channels. Noise Enable must be ON for the Hum control to function.

The default value of 0 dB for Hum is the actual modeled level in the original hardware. This default value can be offset by ± 25 dB.

The Hum frequency is dependent on the Emphasis EQ control (page 27). The frequency is 60 Hz when set to NAB (US) and 50 Hz when set to CCIR (European).

When Tape Speed is set to 30 IPS, the green Emphasis EQ LEDs are not illuminated (and cannot be switched), indicating that the Emphasis EQ is set to AES. However, the Hum frequency can still be set for 30 IPS mode by setting Emphasis EQ to NAB (for 60 Hz) or CCIR (for 50 Hz) prior to setting Tape Speed to 30 IPS.

Note: When Tape Speed is 3.75 IPS, only 60 Hz is available.

Hiss Hiss determines the amount of tape hiss in the tape playback signal. The default value is 0 dB and can be offset by –25 dB to +50 dB for creative purposes. Noise Enable must be ON for this control to function.

Like the hardware, the amount of hiss is dependent on settings of the various controls and may subtly change based on the values of Path Select, Tape Type, Emphasis EQ, Cal Level, Bias, Playback EQs, and Output Level.

Hiss Level is not affected by automatic calibration, so its level does not change with Tape Speed. When Hiss Level is at its default position (O dB), the amount of hiss present in the signal is as if the Tape Speed is 15 IPS. To emulate the amount of hiss at the other tape speeds, enter the offsets from Table 2.

Table 2. Hiss Level Offsets

Tape Speed	Hiss Level Setting
30 IPS	–8 dB
15 IPS	0 dB
7.5 IPS	12.5 dB
3.75 IPS	17 dB

Note: Because hiss noise is an element of tape playback, Hiss is disabled when Path Select is set to Input.

Wow & Flutter Enable

These buttons are global enable/disable controls for the Wow and Flutter effects. When Wow & Flutter is ON, the level of Wow and Flutter can be independently adjusted using the Wow and Flutter Level controls.

Wow and Flutter are "undesirable" pitch modulations induced by the mechanical components of the tape transport. Wow is a by-product of capstan irregularities, while flutter is a by-product of tape stretching and sticking. Both can be effectively used for creative purposes.

Wow usually refers to very low frequency fluctuations, while Flutter refers to faster fluctuations. Wow and flutter is measured as the percentage of deflection from the original pitch. Both are more pronounced at lower tape speeds.

Note: Wow and Flutter levels change with Tape Speed, but they are not affected by automatic calibration.

Wow Determines the amount of Wow in the signal. Wow & Flutter Enable must be ON for this control to function.

Flutter Determines the amount of Flutter in the signal. Wow & Flutter Enable must be ON for this control to function.

Crosstalk Enable

These buttons are global enable/disable controls for the Crosstalk Level (XTALK) parameter. When Crosstalk is ON, the amount of Crosstalk can be adjusted using the Crosstalk Level control.

Crosstalk is the amount of signal bleed between the left and right channels. Crosstalk sonics can vary based upon the Tape Speed and Head Width parameters, however the amount of crosstalk does not vary with these settings.

Crosstalk Level

This control determines the amount of signal crosstalk. Crosstalk Enable must be ON for the Crosstalk Level control to function. The default value of -45 dB is the actual modeled level in the original hardware.

The available range is -50 dB to -10 dB. Crosstalk Level is not affected by automatic calibration.

Transformer
EnableThese ON/OFF buttons enable and disable the transformer cir-
cuit of the Ampex ATR-102. For an overview of this feature, see
"Modeled Transformer" on page 22.

Tape Delay

These parameters control the built-in Tape Delay, which creates tape echo effects. For an overview of this feature, see "Tape Delay" on page 22. The Tape Delay controls are not available in the original hardware.

Note: Tape Delay is not available when Path Select is set to Input or Thru, nor when the Manual Calibration Tools are active.
Tape Delay Enable

These buttons are global enable/disable controls for the Tape Delay effect. When Tape Delay is ON, its red numerical display is active, and other Tape Delay parameters can be adjusted.

Dry/Wet Mix

The Dry/Wet pushbuttons control the mix of the Tape Delay effect. The amount of dry and wet signals are displayed as percentages.

Click the Dry button to increase the dry signal level by 1%, or the Wet button to increase the delayed signal level by 1%.

Tip: Hold the Dry/Wet buttons down to rapidly change the mix values. For fine control in increments/decrements of 0.1%, hold down Shift while changing values.

Delay Time

The left and right channel delay times can be independently adjusted with these controls. Click the "+" or "-" buttons to change the delay times in increments of 10 milliseconds. The available range is 0 - 1000 milliseconds.

Tip: Hold the +/- buttons down to rapidly change the delay times. For fine control in increments/decrements of 1 ms, hold down Shift while changing values.

The default Delay Time values depend on the current Tape Speed, and represent the actual delay time that would occur in the physical realm, reflecting the elapsed time between the signal put on tape at the record/sync head and its reproduction at the playback/repro head. These "physical" default times are shown at right.

Delay Time Defaults • 30 IPS: 62 ms • 15 IPS: 124 ms • 7.5 IPS: 248 ms • 3.75 IPS: 496 ms

Important: When the tape speed is changed, the current delay time is changed to reflect the new "physical time" between the sync and repro heads for the new tape speed, and previously set values are lost (see tip below).

Tip: To retain custom delay times when changing Tape Speed, hold Shift when changing Tape Speed.

Manual Calibration Tools

These controls are the suite of tools included to perform manual calibration of the recorder. These UAD-only tools are not in the original hardware. Manual calibration is entirely optional, as the Auto Cal feature can quickly and automatically calibrate the system.

The manual calibration tools consist of an "external" tone generator with multiple test tones and levels, a distortion meter with digital readouts, and a full suite of

modeled Magnetic Reference Laboratory (MRL) alignment tapes.

Note: The Manual Calibration Tools are operational only when Path Select is set to Sync or Repro. Additionally, the tools may not operate in some hosts unless audio is present on the track containing the plug-in and the transport is running. Placing the plug-in on an aux, bus, or master output may eliminate this host limitation.

This section describes the functions of the manual calibration tools. For instructions on how to use the tools to perform a manual system calibration, see the "Manual Calibration Procedure" on page 40.

About MRL Alignment Tapes Alignment tapes are carefully recorded with accurate and consistent flux levels and test tone frequencies. They are constant companions to all well-maintained professional tape machines. Different alignment tapes are required for each tape speed, head width, equalization standard (CCIR/IEC or NAB), and fluxivity level.

> Alignment tapes are required for system calibration and adjustment so that playback of previously-recorded session tapes will have correct and consistent equalization and levels, regardless of when, or where, the session tape was originally recorded.

> After tape playback system EQ and levels are calibrated to match the known-to-be-correct values of the alignment tape(s), the record-side alignment is performed. The entire record/playback system will then have proper EQ and gain structuring.

Magnetic Reference Laboratory ("MRL") is a company that produces alignment tapes. The MRL tapes used in the UAD Ampex ATR-102 are fringing compensated. In-depth discussions about fringing compensation and system alignment are beyond the scope of this manual; thorough resources are available from the MRL website at: http://www.mrltapes.com

Manual Cal Knob

The Manual Cal knob performs two functions: it sets the signal level of the "external" test tone generator for record calibration, and specifies when alignment tapes are to be used for playback calibration.

When set to $-16 \, dB$, $-6 \, dB$, or $+4 \, dB$, a generated sine wave test tone at the frequency specified by the Tones buttons is sent to the input of the record circuitry. This mode emulates sending external test tones into the system. The level of the test tone is set by the knob position and remains static regardless of other parameter values.

When set to MRL, a test tone from the "alignment tape" is sent into the playback circuitry. The MRL frequency is also specified by the Tones buttons, but the levels used are from the calibrated alignment tape. Therefore the MRL tone levels are dependent on other tape parameter values.

Tones The Tones buttons set the frequency of the "external" test tone generator and the MRL tape test tones. Tone frequencies of 50 Hz, 100 Hz, 1 kHz, 2.5 kHz, 5 kHz, 10 kHz, 15 kHz, and 20 kHz are available.

Click a button to specify that frequency; the active frequency's button is shadowed gray as if in the "down" position.

Distortion Meter

DIST % R DIST % L

The red numerical display, between the Manual Cal knob and the Tones buttons, represents the amount (displayed as a percentage) of third harmonic distortion present in each of the left and right channels. This feature can be useful for custom calibration techniques.

When the Manual Cal knob is set to -16 dB, -6 dB, or +4 dB, the value represents third harmonic distortion in the tape playback circuit. Generally speaking, increasing Record (input) will increase distortion while in this mode, as tape saturation increases. If Bias is set very low, distortion may increase at lower Cal Levels.

Note: When the Manual Cal knob is set to MRL, the Distortion Meter is inactive (there is no distortion display in this mode).

Manual Calibration Procedure

Manual calibration tools are provided so expert users can calibrate the system to their preferred methods for obtaining desired results. For example, some technicians may prefer adjustments for lowest distortion at a certain frequency; setting bias for maximum sensitivity (instead of overbiasing); or other non-standard techniques.

The calibration procedure described here is the most commonly used technique, and is the (albeit simplified) method recommended by the Ampex Operation and Service Manual.

Important: Manual calibration is not required to use UAD Ampex ATR-102. Following this procedure will result in the same (or nearly the same) values obtained by simply using the Auto Cal feature.

Tip: When making manual calibration settings, consider disabling Auto Cal so the manually calibrated values are not accidentally lost if any of the controls that force automatic calibration (Tape Type, Tape Speed, Emphasis EQ, and Head Width) are inadvertently modified.

Preparation • Reduce monitoring system volume to avoid loud sine wave Tones.

- Insert UAD Ampex ATR-102 on the DAW output bus (see note below).
- Set Path Select to Repro mode (Sync mode is not supported for manual cal).
- Set left and right Meter Input/Output switches to the "OUTPUT" position.
- Set left and right Meter Peak/VU switches to the "VU" position.
- Set Tape Speed, Tape Type, Cal Level, and Head Width to desired values.
- If Tape Speed is set to 3.75 IPS, set Cal Level to +3 dB.
- Disable Noise Enable (excessive Hiss may contribute to incorrect results).
- Do not change the above settings throughout the procedure.
- For related information, see the Manual Calibration Notes at the end of this chapter.

Note: The Manual Calibration Tools are operational only when Path Select is set to Sync or Repro. Additionally, the tools may not operate in some hosts unless audio is present on the track containing the plug-in and the transport is running. Placing the plug-in on an aux, bus, or master output may eliminate this host limitation.

	To manually calibrate UAD Ampex ATR-102:			
Repro Level Calibration	1. Set the Manual Cal Knob to the "MRL" position. The built-in alignment tape tone will sound and its level can be viewed on the Meters.			
	2. Set the Tones frequency to 1 kHz.			
	3. Adjust Reproduce (output) so the Meters display 0 dB.			
Repro EQ Calibration	4. Set the Tones frequency to 10 kHz.	ŧE.		
	5. Adjust Repro HF (not to be confused with HF EQ) so the Meters display 0 dB.			
	6. Set the Tones frequency to 100 Hz.			
	7. Adjust Repro LF so the Meters display 0 dB (or as close as possible).*			
	*Because the MRL alignment tapes we used have fringing compensation, it may not be possible to increase Repro LF enough to make the meter reach 0 dB at low frequencies. If a flat response is desired, you can switch the Manual Cal knob from MRL mode to the "external" tones then readjust Repro LF for flat response (0 dB) using the external tones instead of the MRL tones.			
	Note: If Repro HF and/or Repro LF EQs are adjusted by a large amount, i may be necessary to recalibrate the output level (steps 1–3).	t		
Record Bias Calibration	8. Set the Manual Cal Knob to the tone level position in Table 3 below (the tone level depends on tape speed).			
	9. Set the Tones frequency to the value in Table 3 below (the frequency depends on tape speed).			
	Table 3. Record Bias Calibration Frequencies and Levels			
	Tape Speed Tone Frequency Tone Level			

3.75 IPS	2.5 kHz	–16 dB
7.5 IPS	5 kHz	–6 dB
15 IPS	10 kHz	+4 dB
30 IPS	20 kHz	+4 dB

10. Adjust Bias throughout its range until the Meters reach the maximum level achievable with the Bias control.*

*If the meters reach their maximum "pinned" value, you may temporarily reduce the Reproduce level to lower the meters, so the maximum achievable level can be accurately viewed (the maximum achievable level may be higher than the pinned value of 3 dB).

11. Increase Bias (clockwise) until the meter level is reduced by -3.5 dB from its maximum (for 3.5 dB of overbias; see Manual Calibration Notes).*

*When calibrating at 3.75 or 7.5 IPS, the tone generator is at a lower level, therefore meter resolution is decreased. To increase meter precision when adjusting bias at the lower tape speeds, consider temporarily increasing the reproduce level.

12. Set the Tones frequency to 1 kHz.

13. Adjust Record (input) so the Meters display the level in Table 4 below (the level depends on tape speed).

Meter Level
–20 dB
–10 dB
0 dB
0 dB

Table 4. Meter Levels for Record and HF EQ Adjustments

Record EQ Calibration

Record Level

Calibration

14. Set the Tones frequency to the value in Table 5 below (the frequency depends on tape speed).

Table 5. Record HF EQ Calibration Frequencies and Levels

Tape Speed	Tone Frequency	Tone Level
3.75 IPS	5 kHz*	–16 dB
7.5 IPS	10 kHz	–6 dB
15 IPS	15 kHz	+4 dB
30 IPS	20 kHz	+4 dB
*Note: 7.5 kHz is specified in Ampex manual.		

15. Adjust Record HF EQ (not to be confused with Repro HF) so the Meters display the level in Table 4 above (the level depends on tape speed).

Note: If HF EQ is adjusted by a large amount, it may be necessary to recalibrate the record level (steps 12, 13).

The manual calibration procedure is complete.

For related information, see the Manual Calibration Notes in the next section.

Manual Calibration Notes

- O dB on the output meter represents +4 dBm (and -12 dBFS digital) when Reproduce is in its calibrated position, which is marked with the "red arrow sticker."
- For proper calibration, follow the entire calibration procedure in order.
- This example uses 3.5 dB overbias. The amount of gain reduction in step 12 determines the amount of overbias. In some cases we used more than 3.5 dB of overbias to achieve a flatter response.
- Generally speaking, higher Cal Level values will have higher Distortion Meter values for a given reading on the Meters. If Bias is set very low, distortion may increase at lower Cal Levels.
- We recommend leaving the record SHELF EQ control in its default position.
- The Ampex ATR-102 hardware has an additional gain control via a setscrew (like Repro HF/LF, Bias, etc) which is usually used for manual gain calibrations. This control is not available in the plug-in because it would be redundant – the Reproduce control performs the same function.
- We chose to calibrate our reference machine using MRL fringing-compensated calibration tapes, without later adjusting the Repro LF EQ for unity gain using external test tones. Therefore the calibrated values in the plug-in reflect this alignment method. In-depth discussions about fringing compensation and system alignment are beyond the scope of this manual; thorough resources are available from the MRL website at: http://www.mrltapes.com
- Tape Type 111 uses a calibration level of 0 dB. This value is not available in the plug-in, but it can be emulated by setting the CAL level to +3 dB, then reducing the input level (Record knob) by -3 dB and increasing the output level (Reproduce knob) by +3 dB.
- The plug-in operates at an internal level of –12 dBFS. Therefore a digital signal with a level of –12 dB below full scale digital (0 dBFS) at the plug-in input will represent 0 dB on the plug-in meters (if the plug-in is calibrated).
- The included artist presets demonstrate how manual calibration can be used to obtain sonic variations (see "Artist Presets" on page 23).

Tip: For easy recall in future sessions, save unique calibrations as a preset.

Parameter Dependencies

Available Settings Some ATR-102 parameter value ranges depend on the value of other parameters. These dependencies are listed in Table 6 below.

Tape Speed	Head Width	Tape 1	Tape 2	Tape 3	Tape 4	Emphasis EQ
30 IPS	1"	250	456	468	GP9	AES
30 IPS	1/2"	250	456	900	GP9	AES
30 IPS	1/4"	250	456	900	GP9	AES
15 IPS	1"	250	456	468	GP9	NAB
15 IPS	1"	250	456	468	GP9	CCIR
15 IPS	1/2"	250	456	900	GP9	NAB
15 IPS	1/2"	250	456	900	GP9	CCIR
15 IPS	1/4"	250	456	900	GP9	NAB
15 IPS	1/4"	250	456	900	GP9	CCIR
7.5 IPS	1/4"	250	456	35-90	111	NAB
7.5 IPS	1/4"	250	456	35-90	111	CCIR
3.75 IPS	1/4"	250	456	35-90	111	NAB
3.75 IPS	1/4"	250	456	35-90	111	CCIR

Table 6. Ampex ATR-102 parameter dependencies

Ampex ATR-102
LatencyThe Ampex ATR-102 uses an internal upsampling technique to achieve sonic
design goals. This upsampling results in a larger latency than most other UAD
plug-ins. See "Upsampled Plug-Ins" on page 563 for more information.

Original Ampex ATR-102 Mastering Recorder Brochure

API 500 Series EQ Collection

Introduction

The 550A and 560 modular EQs are some of the most popular and enduring mixing and tracking processors ever made. The 500 series modules from API are true industry standards, found in professional multi-channel consoles to Lunchbox racks in the humblest of project studios. Designed by the now legendary Saul Walker in the late 60s, the combination of Walker's 2520 op amp and his Proportional Q circuitry gave the 550 and 560 an uncomplicated way to generate acoustically superior equalization.

Universal Audio now offers the UAD-2 platform true best-in-class emulations of these two audio production staples. With UA's industry-leading circuit modeling that captures the filter shapes, band interactions, and unique filter amplifier clipping behaviors providing full "suspension of disbelief," these plugins fulfill sonic requirements that previously only the API hardware could provide.

Based on vintage units provided by Ross Hogarth and Capitol Studios, both plug-ins provide era-specific features and behaviors, and a remarkable model of API's custom 2520 and output transformer — the results are fantastic lowfrequency transparency and tight imaging, which is that legendary API "punch in your gut" sound. Like with the hardware, the EQs are extremely fast to set, reliable and uniform, and deliver that one-of-a-kind API high headroom precision.

If you want the sound of classic American music, you need the API EQs.

API 500 Series EQ Collection Screenshots

Figure 5. The API 550A EQ (left) and API 560 EQ (right) plug-in windows

Operational Overview

- API 500 Series Collection The API 500 Series EQ Collection includes the UAD API 550A and UAD API 560 plug-ins, which are officially licensed from and endorsed by Automated Processes Inc. Both plug-ins meticulously model the entire electronic path, including custom API 2520 op-amps, transformers, band interactions, and internal clipped filter nonlinearities.
- **API 550A** The API 550A provides reciprocal equalization at 15 points in five steps of boost or cut to a maximum of ± 12 dB of gain at each point. The fifteen fixed equalization points are divided into three overlapping band ranges. The high and low frequency bands are individually selectable to function as either peaking or shelving filters. A bandpass filter may be inserted independently of all other selected equalization settings.
- API 560 The 10 precision EQ bands make the 560 ideal for signal sweetening and mix tuning. The boost and cut characteristics are identical, allowing previous actions to be undone if desired.
- **Proportional Q** The 550A and 560 filters feature API's "Proportional Q" which continuously narrows the bandwidth of the filter as band gain is increased, providing (as stated by API) "an uncomplicated way to generate acoustically superior equalization."
- Artist Presets The API 500 Series EQ Collection includes artist presets from prominent API users. The artist presets are in the internal factory bank and are accessed via the host application's preset menu. The artist presets are also copied to disk by the UAD installer so they can be used within Apollo's Console application. The presets can be loaded using the Settings menu in the UAD Toolbar (see "Using UAD Powered Plug-Ins" in Chapter 7 of the UAD System Manual).
- API 500 Series Latency These plug-ins use an internal upsampling technique to achieve sonic design goals. The upsampling results in a slightly larger latency than most other UAD plug-ins. See "Upsampled Plug-Ins" on page 563 for more information.

API 550A Controls

Band Controls The three EQ bands (HF/MF/LF) are controlled by dual-concentric switches. The inner knob controls the band frequency and the outer knob controls the band gain. Available values for these controls are listed in Table 7 below.

Table 7. API 550A Frequency and Gain Values		
Band	Frequency Values	Gain Values
High Frequency (HF)	5, 7, 10 , 12.5, 15 (kHz)	0 2
Mid Frequency (MF)	0.4, 0.8, 1.5 , 3, 5 (kHz)	4 6 9
Low Frequency (LF)	50, 100, 200 , 300, 400 (Hz)	12 (±dB)
Default values are in bold .		

Frequency

Frequency determines the center frequency of the

band when the filter is in peak mode and the cutoff fre-

quency when the filter is in shelf mode. The frequency for the band can be set using any of these four methods:

- 1. Drag the inner concentric knob to the desired value, or
- 2. Hover over the inner concentric knob then use the mouse scroll wheel, or
- 3. Click directly on the frequency value label to switch to that value, or
- 4. Click on the band label (HF/MF/LF) or units label (kHz/Hz) to cycle through available values.

Gain

The gain for the band can be set using any of these three methods:

- 1. Drag the outer concentric knob handle to the desired value, or
- 2. Click the "+" or "-" text labels to increment/decrement values, or
- 3. Hover over the outer concentric knob then use the mouse scroll wheel, or
- 4. Click directly on the gain value label to switch to that value (this method works only when Controls Mode is set to "Circular" in the UAD Control Panel Configuration panel).

Bandpass Filter	This switch ("FLTR") applies a 50 Hz – 15 kHz bandpass filter to the entire signal. The bandpass filter is completely independent from the from the three main band filters.		
Bell/Shelf Switches	The HF and LF bands are normally in bell mode. When the Bell/Shelf button is engaged for the band (in the darker "down" position), the band is switched to shelving mode.		
	LF Shelf		
	When the LF Shelf button is engaged, the low frequency band is switched to shelving mode.		
	HF Shelf		
	When the HF Shelf button is engaged, the high frequency band is switched to shelving mode.		
Output	This control provides –24 dB to +12 dB of clean uncolored gain at the output of the plug-in.		
	Tip: Click the "0" text label to return Output to the 0 dB position.		
EQ In	The EQ In switch enables the three band filters and the bandpass filter. All filters are active when the switch is engaged and the "IN" LED is il- luminated.		
	When disengaged, the filters are bypassed but other hardware cir- cuitry is still modeled.		
Power	The plug-in is active when the POWER switch is engaged and its associated LED is illuminated. When this switch is off, all plug-in processing is disabled and UAD DSP usage is reduced (unless UAD-2 LoadLock is enabled).		

API 560 Controls

Note: Like the original 560 hardware, the signal is boosted by approximately 1 - 1.5 dB even when all gain sliders are set to 0 dB.

Gain Sliders Each of the 10 sliders controls the gain for one frequency band. Each band can be adjusted to boost or cut the frequency by up to ± 12 dB. The available band frequencies are listed in Table 8 below.

Table 8. API 560 Frequencies

16 kHz 8 kHz 4 kHz
2 kHz 1 kHz
500 Hz
250 Hz 125 Hz
63 Hz
31 Hz

Tip: To return a slider to the 0 dB position, click the slider's frequency text label. To reset all sliders to 0 dB, click the "0" text label above the sliders.

Output

This control provides -24 dB to +12 dB of clean uncolored gain at the output of the plug-in.

Tip: Click the "0" text label to return Output to the 0 dB position.

EQ In The EQ In switch enables the filter sliders. The EQ bands are active when the switch is engaged and the associated "IN" LED is illuminated.

When disengaged, the EQ bands are bypassed but other hardware circuitry is still modeled.

Power

The plug-in is active when the POWER switch is engaged and its associated LED is illuminated. When this switch is off, all plug-in processing is disabled.

Historical Background

API (Automated Processes Inc.) was formed in 1968 with Saul Walker and Lou Lindauer. API is perhaps most noted for their modular approach to equipment manufacturing and for their now legendary 2520 amplifier. To this day, the extraordinary headroom made possible with the 2520 offers consistent analog performance even when using radical EQ curves. API quickly became the leading audio broadcast console manufacturer for radio and television networks and high profile stations. Soon after, recording studios both large and small began using API. The API brand and the company's commitment to excellent audio design endures to this day.

The 550A became API's standard channel module EQ when the company began manufacturing consoles in 1971. As the industry rapidly embraced the sonic quality of the 550A, it quickly found it's way into many custom console designs by Frank DeMedio and other leading engineers. Many of these consoles are still in use today. Forty years later, the 550A remains the standard against which other EQs are measured, and it has played a major role in the recording industry for decades. With virtually all existing units spoken for, popular demand for this EQ resulted in API finally resuming production in 2004.

The API 500 Series EQ Collection Original Hardware

API Vision Channel Strip

Introduction

The API Vision Channel Strip plug-in for the UAD platform is based on API's flagship console found in studios and sound stages across the globe. The plug-in includes five indispensable modern production API modules available in the Vision console: The custom 2520 op-amp based 212L Preamp, 215L Sweep Filters, 550L EQ, 225L Compressor/Limiter, and the 235L Gate/Expander.

The tone of the 212L mic preamp has its roots in the classic API 2488 series all-discrete recording consoles, best known for the famed "LA" sound. The API 212L incorporates the API 2520 op-amp and the same circuit as the legendary API console input modules dating from the 1970s. This mic preamp articulates high frequencies with great detail, while delivering the big sounding, warm bottom end that API is famous for.

With identical features as the modern API 550B EQ, the API 550L (L for "long" frame) is a continuation of the 550A EQs that have played a major role in the history of record making, but with an additional filter band and several new frequencies. The 550L artfully blends the past with the present, and is only available in modern API consoles. Making use of API's "Proportional Q" innovation, the 550L intuitively widens the filter bandwidth at minimal settings and narrows it at higher settings without the need for additional bandwidth controls.

Ideal for almost any application, the widely versatile API 225L Compressor's auto-output level remains at unity regardless of the threshold or ratio settings. This feature allows for real-time adjustments without the need for changing the output level. Both New ("feed-forward") and Old ("feed-back") methods are selectable via the front panel, providing two choices of gain reduction. Soft provides a more subtle compression resulting in a natural sound, while Hard results in a sharp knee type with a severe limiting effect.

The 235L Noise Gate/Expander is one of the fastest noise gates available. The API 235L can reduce noise in any type of program without losing any part of the source. Its extreme flexibility and superb sound make it ideal for all recording or mixing studio applications. The Expander function uses a 1:2 ratio, allowing the signal to "sneak up" to the full signal level without any loss of "under threshold" vocal or percussion nuances. Setting the threshold in the Gate function to the desired level, then switching to the Expander mode is the perfect workflow.

The API 215L is a unique passive, sweepable cut filter, designed specifically to contour the sound in a way that preserves the natural tone of the signal. The 215L is a low pass filter with a slope of 6 dB per octave, and a high pass filter with a slope of 12 dB per octave. The filters are isolated from each other with the same discrete transistor buffer used in the famous 550 series equalizers.

API Vision Channel Strip Screenshot

Figure 6. The API Vision Channel Strip plug-in window

Operational Overview

- **Modular Design** Like the original hardware, the API Vision Channel Strip plug-in has a modular design. Each module controls a different signal processing function, and associated controls are grouped within each module. The following modules are contained in the API Vision Channel Strip plug-in:
 - 212L Microphone Preamplifier
 - 215L High/Low Sweep Filters
 - 235L Gate/Expander
 - 225L Compressor/Limiter
 - 550L Four-Band Equalizer

Signal Flow A simplified view of the default signal flow routing within the plug-in is illustrated in the diagram below. The audio path is shown with solid lines, and the side chain control keys for the dynamics modules are shown with dotted lines.

Figure 7. Simplified default signal flow within the API Vision Channel Strip

The signal flow can be re-routed via options in the plug-in. The 550L EQ can be placed before the dynamics modules via the PREDYN (pre-dynamics) button, and the 215L and/or 550L modules can be moved out of the audio path and into the dynamics side chain path via the SC (side chain) buttons in those modules.

Note that the side chains for the dynamics modules are in series by default (as in diagram above). However, when the 215L and/or 550L are moved into the side chain (via the SC buttons), the side chain inputs for the dynamics modules are in parallel, as shown in the diagram below.

Figure 8. Simplified signal flow illustrating parallel side chain inputs with 215L SC enabled

Displayed
ValuesKnob settings, when compared to the graphical user interface silkscreen num-
bers, may not match the actual parameter values. For example, in the 215L
Sweep Filters module, the highest value shown in the plug-in window is 20
kHz. However, the actual value when the knob is at maximum is 40 kHz.

This behavior is identical to the original hardware, which is modeled exactly. When the plug-in is viewed in parameter list mode (controls and/or automation views), the actual parameter values are displayed.

Artist Presets The API Vision Channel Strip includes artist presets from prominent API users. The artist presets are in the internal factory bank and are accessed via the host application's preset menu. The artist presets are also placed by the UAD installer so they can be used within Apollo's Console application. The presets can be loaded using the Settings menu in the UAD Toolbar (see "Using UAD Powered Plug-Ins" in Chapter 7 of the UAD System Manual).

> This plug-in includes additional artist presets that are not available in the internal factory bank. These additional presets can also be accessed using the Settings menu in the UAD Toolbar.

Unison™ Integration The API Vision Channel Strip features Unison mic preamp technology integration with the mic preamp hardware in Universal Audio's Apollo audio interfaces. With Unison, Apollo's ultra-transparent mic preamps inherit all of the unique sonics, input characteristics, and features of the API Vision 212L hardware preamp module.

Note: Unison is active only when the plug-ins are inserted in the unique IN-PUT insert within Apollo's Console application. For complete Unison details, see the Apollo Software Manual.

Realistic Tandem Control

Unison facilitates seamless interactive control of API Vision Channel Strip plug-in settings using Apollo's digitally-controlled panel hardware and/or the plug-in interface. All equivalent preamp controls (gain, pad, polarity) are mirrored and bi-directional. The preamp controls respond to adjustments with precisely the same interplay behavior as the API Vision Channel Strip hardware, including gain levels and clipping points.

Hardware Input Impedance

All Apollo mic preamps feature input impedance switching in analog hardware that can be physically switched by Unison plug-ins for physical, microphone-to-preamp resistive interaction. This impedance switching enables Apollo's preamps to physically match the emulated unit's input impedance, which can significantly impact the sound of a microphone. Because the electrical loading occurs on input, prior to A/D conversion, the realism is faithful to the original target hardware preamp.

Tactile Gain Staging

Apollo's front panel preamp knob can independently adjust the gain and level parameters available within the Unison plug-in via Gain Stage Mode. The gain stage being adjusted can be remotely switched via Apollo, so the gain levels and their associated colorations can be tuned from the hardware knob for precise physical tactile control, all without using the Unison plug-in's software interface.

API Vision Channel Strip Latency These plug-ins use an internal upsampling technique to achieve sonic design goals. The upsampling results in a slightly larger latency (55 samples; 88 samples at 176.4 and 192 kHz) than most other UAD plug-ins. See "Upsampled Plug-Ins" on page 563 for more information.

API Vision Channel Strip Controls

212L Microphone Preamplifier

212L Gain

This knob adjusts the amount of gain applied to the input signal. The available range is 30 dB to 65 dB. The default value is 40.5 dB.

212L Pad

When enabled, the input signal level is attenuated (lowered) by 20 dB. The pad is engaged when the red indicator is lit.

Pad can be used to reduce signal levels when undesirable overload distortion is present at low preamp gain levels.

Note: The 212L Pad is available for both the mic and line inputs.

212L Meter

The Meter indicates the signal level at the output of the 212L preamp module.

212L Phase

The Phase (\emptyset) button inverts the polarity of the signal. The polarity is inverted when the green indicator is lit. Leave the button off (unlit) for normal polarity.

When the plug-in is used in an INPUT insert within Apollo's Console application, software and hardware control of Phase is mirrored. Polarity can be inverted within the plug-in interface or by using Apollo's polarity button.

Unison Impedance

When API Vision Channel Strip is used in an INPUT insert within the Apollo Console application, the hardware input impedance of the Apollo mic preamp is switched to $1.5k \Omega$ (the value of the 212L hardware medule) for physical microphene to preamp resistive inter-

hardware module) for physical, microphone-to-preamp resistive interaction.

215L High/Low Sweep Filters

The 215L offers two sweepable cut filters, one each for low and high frequencies. The original hardware is transformer coupled and uses a passive filter circuit design for smooth tone.

215L Lo-Pass

The Lo-Pass (high cut) filter has a continuous range of 643 Hz to 40.8 kHz. The slope of this filter is 6 dB per octave. The default value is 40 kHz.

215L Hi-Pass

The Ho-Pass (low cut) filter has a continuous range of 12 Hz to 596 Hz. The slope of this filter is 12 dB per octave. The default value is 12 Hz.

215L SC (Dynamics Side Chain)

This button enables the side chain function for the 215L Sweep Filters. When the 215L side chain is active, signal output from the 215L module is removed from the audio path, and is instead routed to control the 235L and 225L dynamics modules in parallel as shown in the diagram below.

Figure 9. Signal flow with 215L Sweep Filters SC enabled

To listen to the side chain key, simply disengage SC to hear the equalized signal.

Note: The 215L module must be enabled for the 215L side chain to function.

215L On

This button enables the 215L module. The module is active when the button's green indicator is lit.

Note: UAD DSP load is reduced when this module is inactive (unless DSP LoadLock is enabled).

235L Gate/Expander

The 235L Gate/Expander module operates in either gate or expansion mode. Two attack speeds and a continuously variable release time are available in both modes.

235L Threshold

Threshold defines the input level at which expansion or gating occurs. The available range is from +25 dB to -45 dB. The default value is 0 dB.

Signals below the threshold level are processed by the module. Signals above the threshold are unaffected. Rotate this control clockwise to increase the gate/expand effect.

235L Depth

Depth controls the difference in gain between the gated/expanded and nongated/expanded signal. Higher values increase the attenuation of signals below the threshold. When set to zero, no gating or expansion occurs. The available range is 0 dB to -80 dB. The default value is -80dB.

Scaled Control

Although the Depth control has a full range of -80 dB, the scale is expanded in the first half of rotation so 0 to -9 dB is available for fine tuning of subtle, undetectable gating. The second half of rotation is from -10 to -80 dB for more drastic noise reduction.

235L Attack

This two-position switch determines how quickly the onset of gating/expansion occurs when the signal exceeds the threshold. Normal (25 milliseconds) and Fast (100 microseconds) settings are available. The default setting is Normal.

235L Release/Hold Knob

The function of Release/Hold knob (R/H) depends on the setting of the Release/Hold switch (Rel/Hld). With both switch settings, the available range of the knob is 50 milliseconds to 3 seconds. The default value is 0.5 seconds.

Note: Hold mode is only available when the 235L module is set to Gate mode with the Gate/Expander switch.

Release

When the input signal drops below the threshold level and the Release/Hold switch is set to Release, this knob sets the amount of time it takes for signals to decay to the Depth level.

Slower release times can smooth the transition that occurs when the signal dips below the threshold, which is especially useful for material with frequent peaks.

Fast release times are typically only suitable for certain types of percussion and other instruments with very fast decays. Using fast settings on other sources may produce undesirable results.

Hold

When the input signal drops below the threshold level and the Release/Hold switch is set to Hold, this knob sets the amount of time that signals are held at normal levels before signals return to the Depth level.

Note: When set to Hold, the release time is fixed at 100 milliseconds.

235L Release/Hold Switch

This two-position switch (REL/HLD) determines the behavior of the Release/Hold knob when the 235L module is set to Gate mode with the Gate/Expander switch. The default value is Release.

Note: This switch is locked in the Release position when the module is in Gate mode (Hold mode is unavailable in Expander mode).

235L Gate/Expander Switch

This switch (GTE/EXP) toggles the module between Gate and Expander modes. The default value is Expander.

GTE

When set to Gate mode, signals below the threshold are attenuated by the Depth amount.

EXP

When set to Expander mode, the gate applies downwards expansion at a fixed 1:2 ratio, with the amount of gain reduction determined by the Depth control.

Expansion allows the signal to "sneak up" to the full signal level without any loss of "under threshold" nuances.

235L Meter

This meter displays, in dB, the amount of gain attenuation (downward expansion) occurring in the 235L module.

235L On

This button enables the 235L module. The module is active when the button's green indicator is lit.

Note: UAD DSP load is reduced when this module is inactive (unless DSP LoadLock is enabled).

225L Compressor/ Limiter

The 225L Compressor/Limiter offers a continuously variable ratio between 1:1 (no compression) and infinity:1 (limiting). Three attack speeds and continuously variable release times are available. A hard/soft knee setting and a unique new/old setting are also available in the module.

225L Threshold

Threshold defines the input level at which compression begins. The available range is +10 dB to -20 dB. The default value is 0 dB.

Signals that exceed the threshold are processed by the Ratio value. Signals below the threshold are unaffected. Rotate this control clockwise to increase the compression effect.

Note: The 225L compressor automatically increases makeup gain to compensate for levels that are reduced during compression. However, just like the original hardware, the plug-in's compensated makeup gain levels are not perfectly linear.

225L Ratio

Ratio defines the amount of gain reduction applied to signals above the threshold. For example, a value of 2 (expressed as a 2:1 ratio) reduces the signal level above the threshold by half, with an input signal level of 20 dB being reduced to 10 dB.

A value of 1 yields no gain reduction. When the control is at maximum (∞), the ratio is effectively infinity to one, yielding the limiting effect. The available range is 1:1 to infinity. The default value is 4:1.

225L Attack

This three-position switch defines the attack time of the compressor. Available values are Fast (2 milliseconds), Medium (18 milliseconds), and Slow (75 milliseconds). The default value is Medium.

225L Release

Release sets the amount of time it takes for processing to cease once the input signal drops below the threshold level. The available control range is 50 milliseconds to 3 seconds.

Note: Actual release times are program dependent.

Slower release times can smooth the transition that occurs when the signal dips below the threshold, which is especially useful for material with frequent peaks. However, if the release is too long, compression for sections of audio with loud signals may extend to sections of audio with lower signals.

Fast release times are typically only suitable for certain types of percussion and other instruments with very fast decays. Using fast settings on other sources may produce undesirable results.

225L Knee

The knee (onset) characteristic of the compressor/limiter can be set to Soft (SFT) or Hard (HRD) with this two-position switch. The default value is Hard.

Soft provides a more subtle compression resulting in a very natural, less compressed sound. Hard results in a more typical, sharp knee type compression that has a more severe limiting effect.

225L Type

The Type control switches the 225L compressor's control side chain signal to use either a feed-back (OLD) or feed-forward (NEW) design, providing two types of gain reduction. The default value is Old.

Compressors typically have a side chain control signal based on either feedback or feed-forward designs. NEW feed-forward gain reduction is typical of newer VCA type compressors that rely on RMS detectors for the side chain circuit. The OLD feed-back method is what most classic compressors use for the side chain circuit.

Note: Unlike the original hardware, side chain processing via the 215L and 550L modules can be performed with this switch in the OLD position (the hardware cannot use side chain filtering with feedback compression).

225L Meter

This meter displays, in dB, the amount of gain attenuation occurring in the 225L module.

225L On

This button enables the 225L module. The module is active when the button's green indicator is lit.

Note: UAD DSP load is reduced when this module is inactive (unless DSP LoadLock is enabled).

550L Four-Band Equalizer The 550L EQ is divided into four frequency bands: High Frequency (HF), High Midrange Frequency (HMF), Low Midrange Frequency (LMF), and Low Frequency (LF).

The 550L features API's "Proportional Q" which continuously narrows the bandwidth of the filter as band gain is increased, providing (as stated by API) "an uncomplicated way to generate acoustically superior equalization." The boost and cut characteristics are identical, allowing previous actions to be undone if desired.

Band Controls

The four EQ bands (HF/HMF/LMF/LF) are controlled by dual-concentric switches. The inner knob controls the band frequency (values in blue text) and the outer knob controls the band gain (values in white text). Available values for these controls are listed in the table below.

Table 9. API 550L Frequency and Gain Values

Band	Frequency Values	Gain Values
High Frequency (HF)	20, 15 , 12.5, 10, 7, 5, 2.5 (kHz)	0
Low Mid Freq (LMF)	12.5, 10 , 8, 5, 3, 1.5 (kHz), 800 (Hz)	2 4
High Mid Freq (HMF)	1000, 700 , 500, 240, 180, 150, 75 (Hz)	6 9 12
Low Frequency (LF)	400, 300 , 200, 100, 50, 40, 30 (Hz)	(±dB)
Default values indicated in bold text above.		

Frequency

Frequency determines the center frequency of the band

when the band is in peak mode (all bands) and the cutoff frequency when the band is in shelf mode (available with HF/LF bands only). The frequency for the band can be set using any of these four methods:

- Drag the inner concentric knob to the desired value
- Hover over the inner concentric knob then use the mouse scroll wheel
- Click directly on the frequency value label to switch to that value
- Click on the band label (HF/HMF/LMF/LF) to cycle through available values (shift+click to cycle in reverse)

Gain

The gain for the band can be set using any of these four methods:

- Drag the outer concentric knob handle to the desired value
- Click the "+" or "-" text labels to increment/decrement values
- Hover over the outer concentric knob then use the mouse scroll wheel
- Click directly on the gain value label to switch to that value (this method works only when Controls Mode is set to "Circular" in the Configuration panel of the UAD Meter & Control Panel application)

Peak/Shelf Switches

The HF and LF bands are in shelf mode by default (switches in "down" position). When the Peak/Shelf switch is engaged for the band (in "up" position), the band is changed to peak mode. The default value is Shelf.

The Pre-Dynamics button ("PREDYN") re-routes the 550L signal. By default, the audio signal is routed into the 550L mod-

ule after dynamics processing. When PREDYN is enabled (when the green indicator is lit), this routing is swapped, and the EQ module precedes the dynamics processors instead.

When 550L PREDYN is active, the dynamics side chain is always tapped after the 550L module, regardless of the state of the 215L module's SC function.

Note: PREDYN has no effect when the 550L's SC button is active.

The effect of the PREDYN button is shown in the diagrams below.

Figure 10. PREDYN routes the 550L before the dynamics modules

HF

PREDYN

Figure 11. The 550L always precedes the side chain tap when PREDYN is active

550L SC (Dynamics Side Chain)

This control enables the side chain function for the 550L EQ. When the 550L side chain is active, signal output from the 550L module is removed from the audio path, and is instead routed to control the 235L and 225L dynamics modules. The default value is Off.

Figure 12. Signal flow with 550L SC enabled

Note: Both the 550L and 215L modules can both be routed simultaneously to the dynamics side chain. In this case, the 215L precedes the 550L in the side chain path, as shown below.

Figure 13. Signal flow with SC enabled in both 215L and 550L modules

550L EQ

This button enables the 550L module. The module is active when the button's green indicator is lit.

Note: UAD DSP load is reduced when this module is inactive (unless DSP LoadLock is enabled).

Global Module Output Meter

The vertical LED-style metering provides a visual indication of relative signal peak levels at the output of the plugin.

SC Link (Side Chain Link)

When the plug-in is used on a stereo signal, this button links the side chains of the left and right channels of the 225L and 235L dynamics modules so both channels are compressed by the same amounts. SC Link is active when the button's green indicator is lit. The default value is enabled.

Linking the side chains prevents signals which appear on only one channel from shifting the stereo image of the output. For example, any large transient on either channel will cause both channels to compress, and the amount of compression will be similar to the amount of compression for a transient which appears on both channels at the same time.

Note: The SC Link button cannot be engaged when the plug-in is used in a monophonic configuration.

Output

This control provides -24 dB to +12 dB of clean uncolored gain at the output of the plug-in. The default value is 0 dB.

Tip: Click the "0" text label to return Output to the 0 dB position.

Power

The plug-in is active when the POWER switch is engaged and its associated LED is lit. When this button is off, all plug-in processing is disabled and UAD DSP usage is reduced (unless DSP LoadLock is enabled).

Historical Background

API (Automated Processes Inc.) was formed in 1968 with Saul Walker and Lou Lindauer. API is perhaps most noted for their modular approach to equipment manufacturing and for their now legendary 2520 amplifier. To this day, the extraordinary headroom made possible with the 2520 offers consistent analog performance even when using radical EQ curves. API quickly became the leading audio broadcast console manufacturer for radio and television networks and high profile stations. Soon after, recording studios both large and small began using API. The API brand and the company's commitment to excellent audio design endures to this day.

The API Vision Console

Bermuda Triangle

The King of Fuzz Distortion

When it comes to unmistakable, classic fuzz/distortion, the Electro-Harmonix Big Muff reins supreme. A stompbox that defies classification and has never gone out of fashion, vintage Big Muffs are prized for powerfully fat sustain, aggressive attack, and an over-the-top sonic personality.

Inspired by the hallowed early '70s "triangle" version of the Big Muff, the Bermuda Triangle plug-in delivers the same bad-ass attitude and fiendish fuzz that has graced classic records and many-a-legend's pedalboard for over four decades.

Now You Can:

- Track through a faithful emulation of the legendary Electro-Harmonix Big Muff with Apollo Twin, DUO, or QUAD
- Conjure violin-like sustain and powerful slabs of fuzz with the same pedal used by David Gilmour, Jack White, and Dan Auerbach
- Add colorful distortion/fuzz textures to guitars, synths, drums, and vocals at mixdown with any UAD-2 hardware
- Get the same circuit interaction, gain range, and clip points of a vintage Big Muff thanks to Unison technology for Apollo Twin, DUO, and QUAD

The Rise of the
MuffThroughout the '70s, the Big Muff found its way onto classic tracks such as the
Isley Brothers' "Who's That Lady (Part 1)," and the Carpenters' "Goodbye to
Love" — featuring a raging Big Muff plugged directly into the board!

Pink Floyd's David Gilmour began using a Big Muff with 1976's Animals, eventually using the pedal to conjure the beautifully lyrical sustain on The Wall's "Comfortably Numb." Sonic mavericks like Adrian Belew relied on the Muff to elicit beastly howls from a Stratocaster, and in the '90s, Smashing

Bermuda Triangle is not affiliated with, sponsored nor endorsed by any companies currently using the Electro-Harmonix Big Muff name. The Bermuda Triangle name is used solely to identify the classic effect emulated by Universal Audio's product.

	Pumpkins' Billy Corgan and Dinosaur Jr.'s J. Mascis used the Big Muff to de- liver bludgeoning, influential riffs. In more recent years, Jack White and the Black Keys' Dan Auerbach have also used the Big Muff as their go-to distor- tion.
A Faithful Fuzz Emulation	The Bermuda Triangle plug-in expertly captures the original Big Muff's huge sounding bass response and rich-yet-raspy character. Its simple Volume, Tone, Sustain control set allows you to easily and intuitively dial-in single-coil or humbucker-equipped guitars.
Triangle Tones	Whether it's violin-like sustain for lead lines, or bursts of punishing low-string riffs, the Bermuda Triangle plug-in is voiced to deliver the fuzzy goods just like the original vintage unit. From heavily saturated to colorfully clipped, the Ber- muda Triangle reacts like the hardware to your touch and picking attack for a bountiful range of distorted delights.
Unison Technology - Key to Tone, Touch, and Feel	The interaction of your instrument and the first pedal in your signal chain is an essential ingredient to capturing a stompbox's unique character and tone. Thanks to Universal Audio's Unison technology, your guitar gets the same circuit interaction, gain range, and clip points of a vintage Big Muff when you plug in to an Apollo Twin, DUO, or QUAD. This gives you the true tone, feel, and response of the original hardware.
Not Just for Guitar	The Bermuda Triangle's signature voice can also be unleashed on bass, drums, vocals – or anything else. Blowout a drum bus with ridiculous amounts of distortion or add grit and edge to a vocal or synth. And by nailing the orig- inal hardware's beefy low-end response, the Bermuda Triangle is an ideal fuzz/distortion tool for bass guitar.

Bermuda Triangle Screenshot

Figure 14. The Bermuda Triangle plug-in window
Using Bermuda Triangle

Standard DAW Inserts In much the same way as some premier recording and mix engineers use stomp boxes in a mix, Bermuda Triangle can be used for creative purposes on any source signal by placing it in any plug-in insert within a DAW. For typical guitar tones, follow the pedal with a guitar amp emulation (as one would with a hardware guitar pedal and amp).

> Because the plug-in accurately models the original hardware's high-impedance operating levels, precautions may need to be taken to avoid undesirable input clipping.

> **Note:** Since Hi-Z devices typically operate at much lower signal levels than line-level devices, signal levels being routed into the pedal may need to be reduced to avoid undesirable input distortion.

Unison™ Technology with Apollo Bermuda Triangle features Unison technology for integration with the high-impedance input hardware in Universal Audio's Apollo audio interfaces. With Unison, Apollo's Hi-Z inputs inherit all of the unique circuit interaction, gain range, and clip points of the original guitar pedal.

Hi-Z Signal Routing

For the most authentic stompbox tones, plug any high-impedance instrument (guitar, bass, etc.) into Apollo's Hi-Z instrument input and place the pedal plug-in into the unique Unison INPUT insert on the same channel within Apollo's Console application. If desired, follow the Unison pedal plug-in with another pedal or guitar amp emulation in Console's standard insert slots.

This Hi-Z workflow enables near-zero latency monitoring or recording with the same input characteristics and dynamic response as the original pedal.

Note: This plug-in can be Unison-enabled with Apollo's Mic or Line inputs. However, because the original hardware has a high-impedance instrument input only, Apollo's Hi-Z input and Unison insert will provide the most accurate sound and experience of the hardware pedal that is modeled.

Important: Unison is active only when the pedal plug-in is placed in the unique INPUT insert available on Hi-Z inputs within Apollo's Console application. For complete Unison details, see the Apollo Software Manual.

Tactile Control

Apollo's front panel preamp knob can independently adjust the Volume, Sustain, and Output controls available within the Unison pedal plug-in via Gain Stage Mode. The control being adjusted can be remotely switched via Apollo, so the control levels and their associated colorations can be tuned from the hardware knob for precise physical tactile control, all without using the Unison plug-in's software interface.

Bermuda Triangle Controls

Sustain varies the amount of signal overdrive. Rotate the control clockwise to increase distortion and sustain.

Volume Volume adjusts the pedal's modeled output level. Rotate the control clockwise to increase the volume.

Tone	Tone adjusts the high-frequency content of the signal. Rotate the control clockwise to increase the filter amount, which reduces treble content.
Power	The stomp switch toggles between plug-in enable and disable. Click the switch to toggle the Power state.
	Like the original hardware, this is a true-bypass control. When disabled, the signal is not colored by the circuitry.
	Tip: Power can also be toggled by clicking the UA diamond logo.
Output	Output controls the clean (unmodeled) gain at the output of the plug-in. The available range is -24 dB to +12 dB.
	Tip: Click the "U" label to return the control to zero dB.

CHAPTER 6

Cambridge EQ

Overview

The UAD Cambridge EQ plug-in is a mastering-quality, no-compromise equalizer that enables powerful tonal shaping of any audio source. Its algorithm was modeled from various high-end analog filters, providing a sonically rich foundation for timbral manipulation. Special attention was given to the handling of higher frequencies, resulting in a much smoother and more satisfying high-end response than is found in most digital filters.

Cambridge EQ is highly flexible, offering a broad spectrum of options facilitating surgical precision and delivering superior aural results in every application. This may be the most satisfying, full-featured equalizer in your arsenal of creative tools.

Cambridge EQ Screenshot

Figure 15. The UAD Cambridge EQ plug-in window

Cambridge EQ Controls

Each feature of the Cambridge EQ interface is detailed below.

Response Curve Display The Response Curve Display plots the frequency response of the current Cambridge EQ settings. It provides instant visual feedback of how audio is being processed by the equalizer.

Figure 16. Cambridge EQ Response Curve display

The entire audio spectrum from 20 Hz to 20 kHz is displayed along the horizontal axis. Gain and attenuation of frequencies (up to ± 40 dB) are displayed along the vertical axis. The vertical resolution of this display can be modified with the Zoom buttons.

Response Curve Color

The color of the response curve depends on the value of the A/B Selector control. When A is active, the curve is yellow. When B is active, the curve is green (see "A/B Selector Button" on page 78). When Cambridge EQ is disabled, the response curve is grey. **Zoom Buttons** The vertical scale of the Curve Display can be increased or reduced with the Zoom buttons. This function allows the resolution of the Curve Display to be changed for enhanced visual feedback when very small or very large amounts of boost or cut are applied. Four vertical ranges can be selected with the Zoom buttons: ±5, ±10, ±20, and ±40 dB.

Figure 17. Vertical resolution of the Response Curve can be changed with the Zoom buttons

Curve Control Bats There are five control "bats" on the curve display. Each bat is color coded and corresponds to each of the five EQ bands. The position of the bat on the curve display reflects the frequency and gain of its corresponding band, even if the band is disabled.

Figure 18. The Curve Control Bats can be used to control EQ band frequency, gain, and Q

The gain and frequency of an EQ band can be modified simultaneously by dragging its bat with the mouse. If a band is disabled when its bat is touched for the first time, the band is enabled.

Note: To modify the Q of a band with its bat, hold down the Control key while dragging vertically.

When a band is enabled, the EQ curve usually touches the bat. However, because the EQ curve always displays the actual frequency response of Cambridge EQ, if two bands are close together in frequency and/or at extreme gain values, the bat may not touch the curve itself. Master Level Knob

This control adjusts the signal output level of Cambridge EQ. This may be necessary if the signal is dramatically boosted or reduced by the EQ settings. The available range is ± 20 dB.

A/B Selector Button

The A/B Selector switches between two separate sets of Cambridge EQ plug-in values. This feature enables easy switching between two completely independent EQ curves which can be useful for comparison purposes or for automating radical timbre changes. Both the A and B curves reside within a single Cambridge EQ preset.

Click the A/B Selector button to switch between the two curves. When A is displayed, the button and the EQ response curve is yellow. When B is displayed, the button and the curve is green.

Note: To reset the A or B curve to a null (flat) response, control-click the A/B Selector button. The active curve will be nulled.

Note: To copy one curve to another, shift-click the button. The active curve will be copied to the inactive curve.

EQ Enable Button

This button enables or disables the Cambridge EQ altogether. You can use this switch to compare the processed settings to that of the original signal, or to bypass the plugin to reduce UAD DSP load (load is not reduced if UAD-2 DSP LoadLock is enabled).

Low Cut / High Cut Filters

The Low Cut and High Cut filters are offered in addition to the five parametric/shelf bands. A wide range of filter types is provided to facilitate tonal creativity. Many filters that are available are represented.

Three controls are offered: Cut Type, Enable, and Frequency. Each control is detailed below.

Cut Type Menu

6 G 20-	20
6 dB / Oct	
12 dB / Oct	
18 dB / Oct	
24 dB / Oct	
30 dB / Oct	-
36 dB / Oct	
Bessel 2	
Bessel 3	
Bessel 4	
Bessel 5 🔨	:0
Bessel 6	
Butterworth 2	ŀ.,
Butterworth 3	
Butterworth 4	
Butterworth 5	
Butterworth 6	
Elliptic 6	74

The Cut Type menu determines the sound of the low and high cut filters. To view the Cut Type menu, click and hold the green cut type button.

Four types of responses are provided: Coincident Pole, Bessel, Butterworth, and Elliptic. The numbers represent the filter order, i.e. Bessel 4 is a fourth-order filter. Each offers a different sound. To select a new cut response, drag to the desired response and release.

The responses are more gentle on filters with lower numbers, and get steeper and more aggressive as the numbers increase. The coincident-pole filters are first-order filters cascaded in series and offer gentle slopes. Bessel filters are popular because of their

smooth phase characteristic with decent rejection. Butterworth filters offer even stronger rejection. The Elliptic setting is about as "brick wall" as you can get. Generally speaking, more phase shifting occurs as the response gets steeper.

Note: UAD DSP usage does increase some as the filters get stronger (unless UAD-2 DSP LoadLock is enabled).

Cut Enable Button This button activates the cut filters. The filters are enabled when the "In" button is green. UAD DSP usage is slightly reduced when the cut filters are disabled (unless UAD-2 DSP LoadLock is enabled).

Cut Frequency Knob This knob determines the cutoff frequency for the Cut filters. The available range is from 20 Hz - 5 kHz for the low cut filter, and 20 Hz - 20 kHz for the high cut filter.

EQ Bands

All five of the EQ bands can be used in parametric or shelf mode. Each band has identical controls, the only difference is the frequency range values.

The function of the controls is similar in both parametric and shelf modes. The two modes are described separately (see "Parametric EQ" on page 81 and "Shelf EQ" on page 84).

Figure 19. The EQ Band controls

Enable Button Each band can be individually engaged with the Enable button. The button is green when the band is enabled. All bands default to disabled. To enable any band, click the Enable button.

You can use these buttons to compare the band settings to that of the original signal, or to bypass the individual band. UAD DSP usage is slightly decreased when a band is disabled (unless UAD-2 DSP LoadLock is enabled).

Frequency Knob This parameter determines the center frequency to be boosted or attenuated by the Gain setting. The available range for each of the five bands is the same for both parametric and shelf modes. The ranges are shown in Table 10 on page 81.

Low Frequencies (LF)	20-400 Hz
Low-Mid Frequencies (LMF)	30-600 Hz
Mid Frequencies (MF)	100-6 kHz
High-Mid Frequencies (HMF)	900-18 kHz
High Frequencies (HF)	2k-20 kHz

Table 10. Available ranges for the Band Frequency parameter

Note: When operating at sample rates less than 44.1 kHz, the maximum frequency will be limited.

Gain Knob This parameter determines the amount by which the frequency setting for the band is boosted or attenuated. The available range is ±20 dB.

Q (Bandwidth) KnobThe behavior of the Q parameter varies depending on the band mode and the gain. For this reason Q is detailed separately in the parametric and shelf mode sections (see "Parametric Q" on page 81 and "Shelf Q" on page 84).

Parametric EQ

A band is in parametric mode when shelf mode is disabled (see "Shelf Enable Button" on page 84). Three types of parametric EQ are available, as determined by the Parametric Type selector.

Parametric Type Selector

TYPE I

EV/EI

The Parametric Type selector changes the response of the band controls to reflect the behavior of various analog equalizers. It is a global control for all 5 bands, and has no effect on the low

and high cut filters. Click the Parametric Type display to rotate between Types I, II, and III.

The filter algorithm is the same in all three parametric types. The difference is in the dependency between the gain and Q parameters. Each parametric type has its own response characteristics.

In Type I mode, the Q remains constant regardless of the gain setting. In Type II mode, the Q increases as gain is boosted, but remains constant as gain is attenuated. In Type III mode, the Q increases as gain is boosted and attenuated. See Figure 20, Figure 21, and Figure 22.

Parametric Q The Q (bandwidth) knob sets the proportion of frequencies surrounding the center frequency to be affected by the gain control. The Q range is 0.25–16; higher values yield sharper slopes.

Note that the Q numeric value in relation to its knob position is warped (i.e. not linear) and varies according to the parametric type.

Type I When set to Type I, the bandwidth remains at a fixed Q regardless of the gain setting for the band; there is no Q/Gain interdependency. In addition, there is a finer resolution of the Q knob in the middle of its range. This makes it easier to achieve subtle bandwidth changes. Note that the Q value and knob positions do not change as the gain is modified. See Figure 20.

Type IIWhen set to Type II, there is a Q/Gain dependency on boost. The bandwidth
increases continuously as the gain is boosted, but not when attenuated. The
Q knob position determines the maximum Q at full gain.

Filter bandwidth is broader at lower boost settings and narrower at higher boost settings. This can produce a smoother, more natural response when boosting filter gain. Note that the Q value increases as gain is boosted but the knob position does not change The Q value is approached as gain increases, and reaches the knob position at maximum gain. See Figure 21.

Figure 21. Parametric Type II response

Type III When set to Type III, there is a Q/Gain dependency on boost and attenuation. The bandwidth increases continuously as the gain is boosted and attenuated. The Q knob position determines the maximum Q at full gain.

> Filter bandwidth is broader at lower gain settings and narrower at higher gain settings. This can produce a smoother, more natural response when adjusting filter gain.

> Note that the Q value increases as gain is increased but the knob position does not change The Q value is approached as gain increases, and reaches the knob position at maximum gain. See Figure 22.

Figure 22. Parametric Type III response

Shelf EQ

Shelf Enable Button

Each band can be switched from parametric mode to shelf mode by clicking the shelf enable button. The button is off by default. To enable shelving on any band, click the shelf button.

The button is green when shelving is enabled. Additionally, the control bat associated with the band has a horizontal shelf indicator line in the response curve display (see Figure 24 on page 85) when shelf mode is active.

Shelf Type Button

When a band is in shelf mode and its Q is above the minimum value, a resonant peak occurs in the filter response. The Shelf Type button affects where this resonant peak occurs in relation to the shelf frequency.

Its purpose is to emulate the response curves of classic highend analog mixing consoles. It's yet another tool to help you find the exact sound you are looking for.

The Shelf Type button places the resonant peak at (A) the edge of the stopband (Figure 23 on page 85), (B) the edge of the passband (Figure 24), or (C) at the edge of the stopband and the passband (Figure 25).

Shelf Q When a band is in shelf mode, the Q knob sets the resonance of the band. The range of the Q knob is 0-100% when in shelf mode.

Note: When a band is in shelf mode, the Gain setting will affect the Q of the band.

When the Q is at its minimum value, there is no resonant peak. The resonance increases and becomes more prominent as the Q is increased. Therefore, for the shelf type to have any effect the Q must be above its minimum value.

Note: In order for this button to have any affect, the band must be in shelving mode, some gain must be applied, and the Q must be above its minimum value.

Figure 23. Shelf Type A

Figure 25. Shelf Type C

CHAPTER 7 Cooper Time Cube

Dual Mechanical Delay Line

The original Cooper Time Cube was a Duane H. Cooper and Bill Putnam collaborative design that brought a garden hose-based mechanical delay to the world in 1971 and has achieved cult status as the most unique delay ever made. The Cooper Time Cube is famous for its spectacular short delay and doubling effects and its uncanny ability to always sit perfectly in the mix. However, the CTC had limited practicality as a full-featured delay; only 14, 16 or 30 ms settings were available. Over the years this quirky device has grown a strong following and finds a home in the most prestigious studios in the world, such as Blackbird and Sunset Sound. Top producers and engineers such as Richard Dodd, Vance Powell and Joe Chicarelli still swear by the Cooper Time Cube for its unique character.

The Cooper Time Cube MkII has all the sound of the original delay system design and offers all the necessary features expected from a modern delay device. The distinct sound of the single or double hose Coil is preserved regardless of delay setting, and either sound is available at the flick of a switch. The Cooper time Cube MkII also incorporates other enhanced tone shifting features such as the Color switch that presents the user with the original (A) or "leveled" (B) frequency response, plus tone controls and a 2-Pole High Pass Filter. Lastly, a switch is presented for soloing the Wet signal, and the Send switch disables the signal being sent into the delay processor.

Cooper Time Cube Screenshot

Figure 26. The UAD Cooper Time Cube plug-in window

Design Overview

The original UREI/Universal Audio Model 920-16 Cooper Time Cube hardware (see "Cooper Time Cube Hardware" on page 91) has two audio channels, A and B. Each channel is transduced to/from a coiled length of plastic tubing which provides the acoustic "sound columns" that define its distinctive sonic character.

The coils for each channel are at fixed but different lengths, which define the available single delay times of 16ms for channel A and 14ms for channel B. The two channels can be cascaded in series via external routing, for a total available delay time of 30ms at reasonable fidelity for its era, which (according to the original product brochure) "brings complete respectability to the heretofore marginally feasible acoustical delay line."

The UAD Cooper Time Cube plug-in has all the vibe of the original, with modern feature enhancements. It is a true stereo plug-in with two independent delay processors. Each channel has its own set of controls, and there are global controls that affect the plug-in overall.

Cooper Time Cube Controls

Global Controls The global controls affect both channels of the processor simultaneously.

Gain Gain controls the signal input level to the plug-in for both A (left) and B (right) channels. Gain affects the combined wet and dry signals.

The available range is ± 15 dB and the 12 o'clock position is unity gain.

HP Filter	The 12 dB per octave high pass filter is used to reduce low frequencies at the input to the delays when desired. The high pass filter affects the delayed (wet) signals only. The available frequency range is from 20 Hz to 12 kHz.
	Turn the knob clockwise to reduce low frequencies into the delay processors. Full processor bandwidth is obtained with the knob in the fully counter-clock- wise position.
Echo A/B	These two "windows" display the current delay times of channels A and B. Displayed values are defined by the Delay parameter ("Delay A/B" on page 90). Delay values can be entered here directly using the text entry method.
	When Sync mode is off, delay times are expressed in milliseconds. When Sync is on, delay times are expressed as a fractional bar value.
	When the beat value is out of range, the value is displayed in parentheses. This occurs in Sync mode when the time of the note value exceeds 2500ms (as defined by the current tempo of the host application).
Sync	This switch engages Sync mode for both channels of the plug-in. In Sync mode, delay times are synchronized to (and therefore dependent upon) the master tempo of the host application. When Sync is toggled, parameter units are converted between milliseconds and beats to the closest matching value.
	See "Tempo Sync" in Chapter 8 of the UAD System Manual for detailed in- formation about tempo synchronization.
Send	Send determines whether or not signals are sent into the delay processors. When Send is ON, the input signals are delayed. When OFF, the delay in- puts are muted.
Coils	When both coiled tubes of the original hardware are cascaded to increase the available delay time (when both channels are serially connected), the son- ics are slightly different than when only one coil is used. The Coils switch tog- gles between these two sounds available on the hardware, regardless of the Delay value.
	Tip: Longer decays are available when Coils value is set to 1.

Color	The Color switch toggles between the original filter emphasis of the hardware in position A and the "leveled" filter in position B which allows for greater De- cay ranges.
	Unlike the other parameters, the A and B labels for Color are for reference only. They do not represent the left and right channels.
	Note: Color can be subtle, and its affect can vary depending on the value of Coils and/or Decay.
Treble	Treble controls the high frequency response in the delayed portion of the sig- nals. It does not affect the dry signal. Treble is a cut/boost control; it has no effect when in the 12 o'clock position.
Bass	Bass controls the low frequency response in the delayed portion of the sig- nals. It does not affect the dry signal. Bass is a cut/boost control; it has no ef- fect when in the 12 o'clock position.
Wet Solo	The Wet Solo switch puts the Cooper Time Cube into "100% Wet" mode. When Wet Solo is on (in the "up" position), it mutes the dry unprocessed signal.
	Wet Solo is optimal when the plug-in is used on an effect group/bus that is configured for use with channel sends. When the plug-in is used on a channel insert, this control should be deactivated.
	Note: Wet Solo is a global (per plug-in instance) control. Its value is saved within the host project/session file, but not within individual preset files.
Power	The Power switch determines whether the plug-in is active. It's useful for com- paring the processed sound to the original signal.
Meter	The VU Meter provides a visual indication of the output level of the plug-in (the meter is not calibrated). The meter needle drops to minimum when the plug-in is disabled with the Power switch.

Channel Controls

The channel controls affect each channel of the processor independently. The control functionality is identical for each channel. "A" indicates the left channel and "B" is the right channel.

Figure 28. The channel controls

Delay A/B Delay controls the delay time for each channel of the processor. The selected value is shown in the Echo display ("Echo A/B" on page 88).

The available delay range for each channel is 5 milliseconds to 2.5 seconds (2500ms). When Sync is active, beat values from 1/64 to 3/1 can be selected.

When the beat value is out of range, the value is displayed in parenthesis. This occurs in Sync mode when the time of the note value exceeds 2500ms (as defined by the current tempo of the host application). See "Temp Sync" in Chapter 8 of the UAD System Manual for detailed information about tempo synchronization.

Tip: Click the knob then use the computer keyboard arrow keys to increment/decrement beat values in Sync mode.

- **Decay A/B** Decay sets the amount of processed signal fed back into its input (feedback). At the minimum value, one delayed repeat is heard. Higher values (clockwise) increase the number of repeats and intensity of the processed signal, with "near infinite" repeats available at the maximum setting.
- **Pan A/B** Pan sets the position of the delayed (wet) signal in the stereo field; it does not affect the unprocessed (dry) signal.

Tip: Click the "PAN" label text to return the control to center.

Note: When the plug-in is used in a mono-in/mono-out ("MIMO") configuration, the Pan knobs do not function and cannot be adjusted.

Echo Volume A/BThis control determines the volume of the delayed signal. Rotate the control clockwise for louder echo. Up to +10 dB of gain is available at the maximum setting. Reducing the control to its minimum value will mute the delay.

Tip: Click the "ECHO VOL" label text to mute/unmute the delayed output.

Figure 30. The opened acoustic module and the complete system

CHAPTER 8

CS-1 Channel Strip

Overview

The CS-1 Channel Strip provides the EX-1 Equalizer and Compressor, DM-1 Delay Modulator, and RS-1 Reflection Engine combined into one plug-in. Individual effects in the CS-1 Channel Strip can be bypassed when not in use to preserve UAD DSP use.

The CS-1 effects can also be accessed individually by using the individual plug-ins. This is useful if you want to use the plug-ins in a different order, or if you want to use multiple instances of the same plug-in (such as a flange routed to a ping-pong delay with the DM-1 plug-in).

Figure 31. The CS-1 Channel Strip plug-in window

EX-1 Equalizer and Compressor

Figure 32. The EX-1 EQ/Compressor plug-in window

EX-1 Equalizer Controls

The Equalizer portion of the EX-1 is a five-band fully parametric EQ. Each band has its own set of controls. The first two bands can also be enabled to function as low-shelf or high-pass filter. Similarly, the last two bands can be enabled to function as either a high-shelf or low-pass filter.

Band Disable
ButtonEach band can be individually deactivated with the Band Disable button. All
bands default to enabled (brighter blue). To disable any band, click the Dis-
able button. The button is darker blue when the band is disabled.

You can use these buttons to compare the band settings to that of the original signal, or to bypass the individual band.

Gain (G) Knob	The Gain control determines the amount by which the frequency setting is boosted or attenuated. The available range is ±18 dB.
Frequency (fc) Knob	Determines the center frequency to be boosted or attenuated by the Gain set- ting. The available range is 20 Hertz to 20 kiloHertz. When operating at sample rates less than 44.1kHz, the maximum frequency will be limited.
Bandwidth (Q) Knob	Sets the proportion of frequencies surrounding the center frequency to be af- fected. The Bandwidth range is 0.03–32; higher values yield sharper bands.
	In either of the first two bands, when the Bandwidth value is at minimum the band becomes a low-shelf filter, and at maximum the band becomes a high- pass filter.
	Similarly, in either of the last two bands, when the Bandwidth value is at min- imum the band becomes a high-shelf filter, and at maximum the band be- comes a low-pass filter.
Enable/Bypass Switch	Globally enables or disables all bands of the Equalizer. You can use this switch to compare the EQ settings to the original signal or bypass the entire EQ section to reduce UAD DSP load (unless <i>UAD-2 DSP LoadLock</i> is enabled).
Output Knob	Adjusts the signal output level of the plug-in. This may be necessary if the sig- nal is dramatically boosted or reduced by the EQ and/or compressor set- tings.

EX-1 Compressor Controls

- Attack Knob Sets the amount of time that must elapse, once the input signal reaches the Threshold level, before compression will occur. The faster the Attack, the more rapidly compression is applied to signals above the Threshold. The range is 0.05 milliseconds to 100.00 milliseconds.
- **Release Knob** Sets the amount of time it takes for compression to cease once the input signal drops below the Threshold level. Slower release times can smooth the transition that occurs when the signal dips below the threshold, especially useful for material with frequent peaks. However, if you set too large of a Release time, compression for sections of audio with loud signals may extend to lengthy sections of audio with lower signals. The range is 25 milliseconds to 2500 milliseconds (2.5 seconds).

Ratio Knob	Determines the amount of gain reduction used by the compression. For example, a value of 2 (expressed as a 2:1 ratio) reduces the signal by half, with an input signal of 20 dB being reduced to 10 dB. A value of 1 yields no compression. Values beyond 10 yield a limiting effect. The range is 1 to Infinity.
Threshold Knob	Sets the threshold level for the compression. Any signals that exceed this level are compressed. Signals below the level are unaffected. A Threshold of 0 dB yields no compression. The range is 0 dB to -60 dB.
	As the Threshold control is increased and more compression occurs, output level is typically reduced. However, the EX-1 provides an auto-makeup gain function to automatically compensate for reduced levels. Adjust the Output level control if more gain is desired.
Meter Pop-up Menu	Determines whether the VU Meter monitors the Input Level, Output Level, Gain Reduction, or Meter Off. Click the menu above the meter display to select a different metering function.
Enable/Bypass Switch	Enables or disables the Compressor.You can use this switch to compare the compressor settings to that of the original signal or bypass the entire compressor section to reduce UAD DSP load (unless UAD-2 DSP LoadLock is enabled).
Compressor Output Knob	Adjusts the signal output level of the plug-in.

EX-1M Overview

The EX-1M is a monophonic version of EX-1 that enables independent left and right EQ settings in master effects chains and allows Logic Audio users to conserve UAD DSP resources.

EX-1M requires half the processing power compared to that of EX-1 when used on a mono audio track within Logic Audio. Therefore, EX-1M should be used on monophonic audio tracks within Logic whenever possible to conserve UAD resources.

DM-1 Delay Modulator

Figure 33. The DM-1 Delay Modulator plug-in window

The DM-1 Delay Modulator provides stereo effects for delay, chorus, and flange.

DM-1 Controls

Sync Button	This button puts the plug-in into Tempo Sync mode. See Chapter 8 in the UAD System Manual for more information.
L-Delay Knob	Sets the delay time between the original signal and the delayed signal for the left channel. When the Mode is set to one of the delay settings, the maximum delay is 300 msec. When the Mode is set to one of the chorus or flange set- tings, the maximum delay is 125 msec.
R-Delay Knob	Sets the delay time between the original signal and the delayed signal for the right channel. When the Mode is set to one of the delay settings, the maximum delay is 300 msec. When the Mode is set to one of the chorus or flange settings, the maximum delay is 125 msec.
	In the flanger modes, the L and R delay controls have slightly different func- tions than when in the chorus modes. The high peak of the flanger is con- trolled by the settings of the L and R delay controls. The low Peak of the flanger is determined by the setting of the Depth control.
	When delay times longer than 300ms are desired, use the DM-1L plug-in in- stead. DM-1L has a maximum time of 2400ms per channel.

Mode Pop-up Menu	Determines the DM-1 effect mode. The available modes are: Chorus, Chorus180, QuadChorus, Flanger1, Flanger2, Dual Delay, and Ping Pong Delay. In addition to reconfiguring the DM-1's settings, the Mode also deter- mines the available parameter ranges for L/R Delay and Depth.
	In Chorus mode, both oscillators (or modulating signals) are in phase.
	In Chorus 180 mode, both oscillators (the modulating signals) are180 de- grees out of phase (inverted).
	In QuadChorus mode, both oscillators (the modulating signals) are 90 de- grees out of phase.
	In Ping Pong delay mode, you will only get a ping-pong effect if you have a mono source feeding the DM-1 on a stereo group track or send effect. On a mono disk track, it works exactly like Dual Delay.
Rate Knob	Sets the modulation rate for the delayed signal, expressed in Hertz.
Depth Knob	Sets the modulation depth for the delayed signal, expressed as a percentage.
	In Dual Delay and Ping Pong Delay modes, adjusting the Depth and Rate con- trols can offer some very otherworldly sounds.
LFO Type Pop-up Menu	Determines the LFO (low frequency oscillator) waveshape and phase used to modulate the delayed signal. The waveshape can be set to triangle or sine, each with a phase value of 0, 90, or 180-degrees.
Recirculation (RECIR) Knob	Sets the amount of processed signal fed back into its input. Higher values in- crease the number of delays and intensity of the processed signal.
	Recirculation allows both positive and negative values. The polarity refers to the phase of the delays as compared to the original signal. If Recirculation dis- plays a positive value, all the delays will be in phase with the source. If it dis- plays a negative value, then the phase of the delays flips back and forth be- tween in phase and out of phase.
	In the flanger mode, Recir has the potential to make some very interesting sounds. Try turning RECIR fully clockwise or counter-clockwise, and set the de- lay to very short but different values.

	The RECIR units are expressed as a percentage in all Modes except Dual De- lay and Ping Pong. In these modes, RECIR values are expressed as T60 time, or the time before the signal drops 60 decibels.
Damping Knob	This low pass filter reduces the amount of high frequencies in the signal. Turn down this control to reduce the brightness. Higher values yield a brighter sig- nal. Damping also mimics air absorption, or high frequency rolloff inherent in tape-based delay systems.
Wet/Dry Mix Knob	This control determines the balance between the delayed and original signal. Values greater than 50% emphasize the wet signal, and values less than 50% emphasize the dry signal. A value of 50% delivers equal signals. A value of 0% is just the dry signal.
	Wet/Dry Mix allows both positive and negative values. The polarity refers to the phase of the delays as compared to the original signal. If a positive value is displayed, then all the delays will be in phase with the source. With a neg- ative value, the delayed signal is flipped 180 degrees out of phase with the source.
L-Pan Knob	Sets the stereo position for the left channel, allowing you to adjust the width or balance of the stereo signal. For a mono signal, L-Pan behaves as the level control for the left delay tap.
R-Pan Knob	Sets the stereo position for the right channel, allowing you to adjust the width or balance of the stereo signal. For a mono signal, R-Pan behaves as the level control for the right delay tap.
Enable/Bypass Switch	Enables or disables the Delay Modulator. You can use this switch to compare the DM-1 settings to the original signal or bypass the entire DM-1 section to reduce UAD DSP load (load is not reduced if UAD-2 DSP LoadLock is en- abled).
Output Knob	Adjusts the signal output level of the plug-in.
DM-1L	
	DM-1L is identical to the DM-1 except that the maximum available delay time per channel is 2400milliseconds. DM-1L requires significantly more memory resources of the UAD than the DM-1. Therefore, we recommend using the DM- 1L only when very long delay times are needed.

Link Button This button links the left and right delay knobs so that when you move one delay knob, the other follows. The ratio between the two knobs is maintained.

Figure 34. The DM-1L includes a Link button

RS-1 Reflection Engine

Overview

Figure 35. The RS-1 Reflection Engine plug-in window

The RS-1 Reflection Engine simulates a wide range of room shapes, and sizes, to drastically alter the pattern of reflections. While similar to that of the RealVerb Pro plug-in, the RS-1 does not offer the same breadth of features (such as room hybrids, room materials, morphing, and equalization). However, if you do not need the advanced capabilities that RealVerb Pro offers, you can use the RS-1 to achieve excellent room simulations, while also preserving DSP resources on the UAD device.

> The Delay control sets the time between the direct signal and the first reflection. The Size parameter controls the spacing between the reflections. The Recir control affects the amount of reflections that are fed back to the input and controls how many repeats you hear.

RS-1 Controls

Sync Button This button puts the plug-in into Tempo Sync mode. See Chapter 8 in the UAD System Manual for more information.

Shape Pop-up
MenuDetermines the shape of the reverberant space, and the resulting reflective
patterns.

Cube	Square Plate
Box	Rectangular Plate

Cylinder	Circular Plate
Dome	Echo
Horseshoe	Ping Pong
Fan	Echo 2
Reverse Fan	Fractal
A-Frame	Gate 1
Spring	Gate 2
Dual Spring	Reverse Gate

Table 11. Available RS-1 Shapes

Delay Knob	Sets the delay time between the original signal and the onset of the reflec- tions.
Size Knob	Sets the size of the reverberant space (from 1–99 meters) and defines the spacing of the reflections.
Delay/Size Settings Interaction	You may notice that when Delay is set to its maximum value and the Size con- trol is moved to its maximum value, the Delay value is decreased, and vice versa. This occurs because the maximum delay time available to the plug-in has been reached — the available delay time is limited and is divided among the Delay and Size values. Therefore, if the value of the Delay or Size setting is increased towards maximum when the other control is already high, its complementary setting may be reduced.
Recirculation (RECIR) Knob	Sets the amount of processed signal fed back into its input. Higher values in- crease the number of reverberations/delays and intensity of the processed signal.

Recirculation allows both positive and negative values. The polarity refers to the phase of the delays as compared to the original signal. If Recirculation displays a positive value, all the delays will be in phase with the source. If it displays a negative value, then the phase of the delays flips back and forth between in phase and out of phase.

- **Damping Knob** This low pass filter reduces the amount of high frequencies in the signal. Turn down this control to reduce the brightness. Higher values yield a brighter signal. Damping also mimics air absorption, or high frequency rolloff inherent in tape-based delay systems.
- Wet/Dry Mix
KnobThis control determines the balance between the delayed and original signal.
Values greater than 50% emphasize the wet signal, and values less than 50%
emphasize the dry signal.

Wet/Dry Mix allows both positive and negative values. The polarity refers to the phase of the delays as compared to the original signal. If a positive value is displayed, then all the delays will be in phase with the source. With a negative value, the delayed signal is flipped 180 degrees out of phase with the source.

- **L-Pan Knob** Sets the stereo position for the left channel, allowing you to adjust the width or balance of the stereo signal. For a mono signal, set both the L-Pan and R-Pan to the left.
- **R-Pan Knob** Sets the stereo position for the right channel, allowing you to adjust the width or balance of the stereo signal. For a mono signal, set both the L-Pan and R-Pan to the left.
- Enable/BypassEnables or disables the Reflection Engine. You can use this switch to compare
the RS-1 settings to the original signal or bypass the entire RS-1 section to re-
duce UAD DSP load (load is not reduced if UAD-2 DSP LoadLock is enabled).
- **Output Knob** Adjusts the relative output of the plug-in.

CHAPTER 9

dbx 160 Compressor/Limiter

Overview

The dbx® 160 Compressor/Limiter is an officially licensed and faithful emulation of the legendary dbx 160 hardware compressor/limiter — still widely considered the best VCA compressor ever made. Originally designed and sold by David Blackmer in 1971, this solid-state design set the standard for performance and affordability. The dbx 160 (commonly referred to as the "VU") is a highly regarded studio staple, famous for its simple control set and firm, distinct compression characteristics. Unlike later monolithic IC units, the "VU" uses a series of discrete components for gain reduction resulting in unique nonlinearities not found in other VCA compressors — a sonic distinction from later models. The UAD Powered Plug-In version of the dbx 160 captures all of the sonic nuances from our "golden" modeling unit, plus the simple control set of the original hardware, including Threshold, Compression (Ratio) and Output Gain. Just like with the hardware, LED threshold indicators are provided in the plug-in, as well the Input/Output/Gain Change VU meter for which the unit is famous.

dbx 160 Screenshot

Figure 36. The dbx 160 plug-in window

dbx 160 Controls

The minimal controls on the UAD dbx 160 make it very simple to operate.

Threshold

The Threshold knob defines the level at which the onset of compression occurs. Incoming signals that exceed the Threshold level are compressed. Signals below the Threshold are unaffected.

The available range is from -55 dB to 0 dB. The numbers on the graphical interface indicate volts, as on the original hardware.

As the Threshold control is decreased and more compression occurs, output level is typically reduced. Adjust the Output Gain control to increase the output to compensate if desired.

Below

Knob

When the input signal is below the compression threshold value, the Below LED illuminates. No compression is occurring when Below is lit.

Above

The Above LED illuminates when the input signal has exceeded the Threshold value, indicating that compression is occurring. The higher the signal is above the Threshold, the brighter the LED glows.

Compression

The Compression parameter determines the ratio for the compressor. Less compression occurs at lower values. The available range is continuous, from 1.00:1 to Infinity:1.

Note: For compression to occur, signals must exceed the Threshold value.

At values above approximately 10:1, the compressor behaves more like a peak-limiter. See "The LA-2 captures one of the earliest Teletronix examples. This exceedingly rare unit preceded the LA-2A by a few years and incredibly, still has the original T4A fully intact. The LA-2 provides the slowest response and a unique "mellowed" sound due to 50 years of luminescent panel aging

inside the T4 module. Use the LA-2 with legato tempos and your most vowellike sources for a transparency and sublime mood unlike any other compressor." on page 518 for more information about compressor/limiter theory of operation.

Output Gain

Output Gain controls the signal level that is output from the plug-in. The available range is ± 20 dB.

Generally speaking, adjust the Output control after the desired amount of compression is achieved with the Threshold and Compression controls. Output does not affect the amount of compression.

Meter Buttons

The Meter buttons define the mode of the VU Meter. The buttons do not change the sound of the signal processor. The active button has a darker appearance when compared to the inactive buttons.

VU Meter

When set to Input, the VU Meter indicates the plug-in input level in dB. When set to Output, the VU Meter indicates the plug-in output level in dB. When set to Gain Change, the VU Meter indicates the amount of Gain Reduction in dB.

Power

The Power switch determines whether the plug-in is active. Click the button to toggle the state. When the Power switch is in the Off (lighter) position, plug-in processing is disabled and UAD DSP usage is reduced (load is not reduced if UAD-2 DSP LoadLock is en-

abled).

CHAPTER 10 DreamVerb

Overview

DreamVerb[™], Universal Audio's unique stereo reverb plug-in, draws on the unparalleled flexibility of RealVerb Pro. Its intuitive and powerful interface lets you create a room from a huge list of different materials and room shapes. These acoustic spaces can be customized further by blending the different room shapes and surfaces with one another, while the density of the air can be changed to simulate different ambient situations.

DreamVerb also features a flexible 5-band active EQ and unique level ramping for the early and late reflections for ultra-realistic dynamic room simulation. And with Universal Audio's proprietary smoothing algorithm, all parameters can be adjusted with automation or in real-time without distortion, pops, clicks, or zipper noise.

DreamVerb provides two graphic menus for selecting preset room shapes. The shapes can be blended according to the demands of your mix. Room materials are selected with two graphic menus containing preset Materials. A third menu specifies the air density for further spectral control. As with the room shapes, the materials and air can be blended as desired.

DreamVerb also includes intuitive graphic control over equalization, timing and diffusion patterns. To maximize the impact of your recording, we put independent control over the direct path, early reflections, and late-field reverberation in your hands.

Capitalizing on the psychoacoustic technology that went into the design of RealVerb Pro, we have incorporated some of these principles into Dream-Verb. Our proprietary Stereo Soundfield Panning allows you to spread and control the signal between stereo speakers creating an impression of center and width. The ability to envelop your listener in a stereo recording is an entirely new approach to reverb design.

Screenshot

Figure 37. The DreamVerb plug-in window

Signal Flow

Figure 38 illustrates the signal flow for DreamVerb. The input signal is equalized then delay lines are applied to the early reflection and late field generators. The resulting direct path, early reflection, and late-field reverberation are then independently positioned in the soundfield.

Figure 38. DreamVerb signal flow

The DreamVerb user interface (Figure 37 on page 106) is similarly organized. Reflected energy equalization is controlled with the Resonance panel. The pattern of early reflections (their relative timing and amplitudes) is determined by the room shapes in the Shape panel (Figure 41 on page 109). Early reflection pre-delay, slope, timing, and amplitude are specified in the Reflections panel (Figure 43 on page 114). The Materials panel (Figure 42 on page 111) is used to select relative late-field decay rates as a function of frequency. The late-field predelay, decay rate, room diffusion, slope, and level is specified in the Reverberation panel (Figure 44 on page 115). Finally, the Positioning panel (Figure 45 on page 117) contains controls for the placement of the source, early reflections, and late-field reverberation.

Resonance (Equalization) Panel

The Resonance panel (Figure 39 on page 108) is a five-band equalizer that can control the overall frequency response of the reverb, effecting its perceived brilliance and warmth. By adjusting its Amplitude and band Edge controls, the equalizer can be configured as shelving or parametric EQs, as well as hybrids between the two.

The EQ curve effects the signal feeding both the early reflections and the late field reverberations, but not the direct path.

Bands 1 and 5 are configured as shelving bands. Bands 2, 3, and 4 also have an Edge control for adjusting its bandwidth.

Generally speaking, a lot of high-frequency energy results in a brilliant reverberation, whereas a good amount of low-frequency content gives a warm reverberation.

Note: The values for the EQ parameters are displayed in the text fields at the bottom of the Resonance panel. The values can also be entered directly using the text entry method.

Figure 39. DreamVerb Resonance panel

- **Bypass** The equalizer can be disabled with this switch. When the switch is off (black instead of grey), the other resonance controls have no effect. This switch has no effect on the direct signal path.
- **Band Amplitude** Each of the five bands has its own amplitude (gain) control. The amplitude range of each band is -30 dB to +20 dB.

To adjust the amplitude of bands 2, 3, and 4, grab the control bat for the band and drag vertically or use the direct text entry method. For bands 1 and 5, drag the horizontal line (these do not have a control bat).

Band Edge Bands 2, 3, and 4 have an Edge control. This parameter effects the bandwidth of the band. To adjust the band edge, grab its control bat and drag horizontally or use the direct text entry method.

> The effect of the band edge on the filter sound can depend upon the settings of the adjacent bands. For example, the sonic effect of this parameter is more pronounced if the amplitude of adjacent bands is significantly different than that of the band whose edge is being adjusted.
Shelving The simplest (and often most practical) use of the equalizer is for low and/or high frequency shelving. This is achieved by dragging the left-most or right-most horizontal line (the ones without control bats) up or down, which boosts or cuts the energy at these frequencies.

Drag these control handles up or down for shelving EQ.

Figure 40. DreamVerb Resonance Shelving Bands

Shape Panel

The parameters in the Shape panel, in conjunction with the Materials panel (Figure 42 on page 111), effect the spatial characteristics of the reverb.

The pattern of early reflections in a reverb is determined by the room shape(s) and the ER start and end points. Two shapes can be blended from 0–100%. All parameters can be adjusted dynamically in real time without causing distortion or other artifacts in the audio. 21 shapes are available, including various plates, springs, rooms, and other acoustic spaces.

Note: The Shape parameters effect only the early reflections. They have no effect on the late field reverberation.

DreamVerb lets you specify two room shapes that can be blended to create a hybrid of early reflection patterns. The first and second shape each have their own menu. The available shapes are the same for each of the two shape menus.

The first shape is displayed in the upper area of the Shape panel, and the second shape is displayed in the lower area.

To select a first or second shape, click its shape pop-up selector menu to view the available shapes, then drag to the desired shape and release.

Shape Blending
BarThe Shape Blending Bar (see Figure 41 on page 109) is used to blend the two
shapes together at any ratio. The two shapes are not just mixed together with
this parameter; the early reflections algorithm itself is modified by blending.

Blend the early reflection patterns of the two rooms by dragging the Blending Bar. Drag the bar to the bottom to emphasize the first shape; drag to the top to emphasize the second shape.

The relative percentages of the two rooms appear at the bottom of the Shape panel. To use only one room shape, drag the Blending Bar so a shape is set to 100%.

The resulting early reflection pattern is displayed at the top of the Reflections panel (Figure 43 on page 114), where each reflection is represented by a yellow vertical line with a height indicating its arrival energy, and a location indicating its arrival time.

Materials Panel

The parameters in the Materials panel, in conjunction with the Shape panel (Figure 41 on page 109) and Reverberation panel (Figure 44 on page 115) effect the spatial characteristics of the reverb.

The material composition of an acoustical space effects how different frequency components decay over time. Materials are characterized by their absorption rates as a function of frequency—the more the material absorbs a certain frequency, the faster that frequency decays.

Note: While materials are used to control decay rates as a function of frequency, the overall decay rate of the late-field reverberation is controlled from the Reverberation panel (see Figure 44 on page 115).

24 real-world materials are provided, including such diverse materials as brick, marble, hardwood, water surface, and audience. Also included are 24 artificial materials with predefined decay rates, and seven air densities.

Note: The parameters in the Materials panel always effect the late-field reverberations. However, the materials parameters effect the early reflections ONLY if the "Filtering" parameter in the Reflections panel (Figure 43 on page 114) is set to a non-zero value.

Figure 42. DreamVerb Materials panel

Materials Menus	DreamVerb lets you specify two room materials, which can be blended to create a hybrid of absorption and re- flection properties. The first and second room material each has its own menu. The available materials are the same for each of the two materials menus.	Air Audience Brick Carpet Cellulose Concrete Block
	The first material is displayed in the lower left area of the Materials panel, and the second material is displayed in the lower right area.	Drapes Fiberglass Glass Window Grass Gravel
	To select the first or second material, click its material pop-up selector menu to view the available materials, then drag to the desired material and release.	Hardwood Linoleum Marble Painted Block
	For a discussion of the various materials, see "About the Materials" on page 449.	Plaster On Brid Plaster On Cond Plate Glass Plywood
	In addition to the "perfect" materials marked with a K, DreamVerb provides "J" materials that are not found in RealVerb Pro. These perform the inverse of the "K" mate- rials. The materials marked with a J preferentially absorb low frequencies; they give the selected decay time at high frequencies, and a much shorter decay time at low frequencies. Inverse Air
Inverse Thick Fog

The more dense the air is, the more it absorbs high frequencies. At the top of the Air Density menu is Ideal Gas, where no frequencies are absorbed. The air quality increases in density with each selection as you go down the menu.

Inverse Air and Inverse Thick Fog absorb more low frequencies instead of high frequencies.

dow ock Bhick Concrete face J0175 Hz J0250 Hz J0350 Hz J0500 Hz J0700 Hz J1.00 KHz J1.40 KHz J2.00 KHz J2.80 KHz J4.00 KHz J5.60 KHz J8.00 KHz

Materials Blending Bars

The Materials Blending Bars (see Figure 42 on page 111) are used to blend the three materials together at any ratio. The materials are not just mixed together with the bars; the reverberation algorithm itself is modified by blending.

Materials Blending

Blend the two materials by dragging the vertical Blending Bar horizontally. Drag the bar to the right to emphasize the first material; drag to the left to emphasize the second material.

The relative percentages of the two materials appear next to each menu in the Materials panel. To use only one material, drag the Blending Bar so a material is set to 100%.

Air Blending

Blend the air density with the materials by dragging the horizontal Blending Bar vertically. Drag the bar to the top to emphasize the solid materials; drag to the bottom to emphasize the air.

The percentage of air used appears next to the Air Density menu. To use only solid materials, drag the horizontal Blending Bar to the top so air is set to 0%. To use only air, drag the horizontal Blending Bar to the bottom so air is set to 100%.

Reflections Panel

The Reflections panel (Figure 43 on page 114) offers control over the timing and relative energies of the reverb early reflections (ER). These parameters effect the reverb's perceived clarity and intimacy. Each early reflection is visually represented by a yellow vertical line with a height indicating its arrival energy and a location indicating its arrival time.

Unique to DreamVerb is independent control of the amplitude at the early reflection start and end points which facilitates envelope shaping of the reflections. This allows the ability to fade-in or fade-out the reflections to more accurately emulate acoustic environments or for special effects.

Note: The values for the Start and End bats are displayed in the text fields at the bottom of the Reflections panel. These values can also be entered directly using the text entry method.

Figure 43. DreamVerb Reflections panel

- BypassThe early reflections can be disabled with this switch. When the switch is off
(black instead of grey), the other Reflections controls have no effect. This
switch has no effect on the direct signal path.Reflections StartThis bat controls two early reflections start parameters. Dragging the bat hor-
izontally controls the ER predelay (the delay between the dry signal and the
- onset of the ER). Dragging it vertically controls the amplitude of the reflections energy at the ER start time.
- **Reflections End** This bat controls two ER end point parameters. Dragging the bat horizontally controls the ER end time (the time at which the ER is no longer heard). Dragging it vertically controls the amplitude of the reflections energy at the end point.
- **Filtering** This parameter determines the amount of filtering from the Materials panel to be applied to the early reflections. The Materials effect upon the ER is most pronounced when Filtering is set to 100%.

Note: The parameters in the Materials panel have no effect on the early reflections unless this parameter value is above 0%.

Late-Field Relative Timing

To highlight the relative timing relationship between the early reflections and late-field reverberation components, the shape and timing of the late-field is represented as an outline in the Reflections panel. The shape of this outline is modified by parameters in the Reverberations panel, not the Reflections panel.

Reverberation Panel

The Reverberation panel (Figure 44) contains the parameters that control the late-field (LF) reverb tail for DreamVerb.

The primary spectral characteristics of the late-field reverberation are determined by the parameters in the Materials panel (page 111) in conjunction with the Reverberation panel settings.

Note: The values for the late-field controls are displayed in the text fields at the bottom of the Reverberations panel. These values can also be entered directly using the text entry method.

Figure 44. DreamVerb Reverberation panel

Bypass The late-field reverberations can be disabled with this switch. When the switch is off (black instead of grey), the other Reflections controls have no effect. This switch has no effect on the direct signal path.

Late-Field Start	This parameter defines when the late-field reverb tail begins (the delay be- tween the dry signal and the onset of the LF) in relation to the dry signal.	
Amplitude & Slope	This bat controls two late-field parameters. Dragging the bat vertically con- trols the maximum amplitude of the LF reverb energy. Dragging it horizontally controls the LF slope (fade-in) time.	
Decay Time	This control effects the length of the reverb tail. Drag the bat to the left for a short decay, or to the right for a long decay.	
Diffusion	This slider effects how quickly the late-field reverberations become more dense. The higher the Diffusion value, the more rapidly a dense reverb tail evolves.	
ER Relative Timing	To highlight the relative timing relationship between the early reflections and late-field reverberation components, the shape and timing of the early reflec- tions is represented as an outline in the Reverberation panel. The shape of this outline is modified by parameters in the Reflections panel, not the Reverbera- tion panel.	

Positioning Panel

DreamVerb has the ability to separately position the direct path, early reflections, and late-field reverberation. The Positioning panel (Figure 45 on page 117) provides panning controls for each of these reverb components. In addition, a proprietary Distance control adjusts perceived source distance. These controls allow realistic synthesis of acoustic spaces—for instance listening at the entrance of an alley way, where all response components arrive from the same direction, or listening in the same alley next to the source, where the early reflections and reverberation surround the listener.

Note: When DreamVerb is used in a mono-in/mono-out configuration, all Positioning controls except Distance are unavailable for adjustment.

Positioning			
Direct	100 L		
			100 R
Early	100 L		100 R
Late	100 L	00	100 R
Distance 23 %			

Figure 45. DreamVerb Positioning panel

Direct These two sliders control the panning of the dry signal. The upper Direct slider controls the left audio channel, and the lower Direct slider controls the right audio channel.

A value of <100 pans the signal hard left; a value of 100> pans the signal hard right. A value of <0> places the signal in the center of the stereo field.

Note: If the DreamVerb "Mix" parameter (page 118) is set to 100% wet or the Wet button is active, these sliders have no effect.

- **Early** This slider, which contains two control handles, adjusts the stereo width of the early reflections.
- Late This slider, which contains two control handles, adjusts the stereo width of the late-field reverberations.

Early & Late Adjustment

The left and right slider handles are dragged to adjust the stereo width. For a full stereo spread, drag the left handle all the way to left and right handle all the way to the right. When the slider handles are not set to maximum width, the center of the slider can be dragged left or right to set the positioning of the signal.

To pan a mono signal hard left or right, drag the slider all the way to the left or right.

Distance DreamVerb allows you to control the distance of the perceived source with this slider. In reverberant environments, sounds originating close to the listener have a different mix of direct and reflected energy than those originating further from the listener.

Larger percentages yield a source that is farther away from the listener. A value of 0% places the source as close as possible to the listener.

Levels Panel

This panel is where DreamVerb input/output levels, wet/dry mix, and reverb mute controls can be modified.

Figure 46. DreamVerb Levels panel

Input Modifies the signal level at the input to DreamVerb. A value of zero is unity gain.

Output Modifies the signal level at the output of DreamVerb. A value of zero is unity gain.

Mute	This switch mutes the signal at the input to DreamVerb. This allows the reverb tail to play out after mute is applied, which is helpful for auditioning the sound of the reverb. Mute is on when the button is gray and off when the button is black.
Mix	The wet and dry mix of DreamVerb is controlled with this slider. The two but- tons above this slider labeled "D" and "W" represent Dry and Wet; clicking either will create a 100% dry or 100% wet mix.
Dry	When this button (labeled "D") is enabled, DreamVerb is 100% dry. It has the same effect as moving the Mix slider to 0%. Dry is on when the button is gray and off when the button is black.
Wet	When this button (labeled "W") is enabled, DreamVerb is 100% wet. It has the same effect as moving the Mix slider to 100%. Wet is on when the button is gray and off when the button is black.

Spatial Characteristics

Size The apparent size of a reverberant space is dependent on many factors. Most reverbs on the market have a "size" parameter, which usually modifies several facets of the reverb algorithm at once. You may notice DreamVerb does not have a "size" parameter. Instead, the elements that control the reverberant space are available to the user.

In DreamVerb, room size is determined by the interaction between all the parameters in the Reflections and Reverberation panels. To get a larger-sounding space, increase the T60 (reverberation time), use proportionally more air, increase the pre-delays, and slightly shift the Resonance transition frequencies to lower values.

Pre-Delay Intimacy and remoteness are largely controlled by the pre-delays. Generally speaking, use shorter pre-delays for more intimate spaces. Clear spaces have most of their energy in the first eighty milliseconds or so; muddy spaces have a lot of late arriving energy.

Space In some sense, Shape determines the spatial characteristics of the reverberator, whereas Materials effects the spectral characteristics.

DreamVerb Presets

DreamVerb includes 100+ presets in addition to the internal factory bank. Presets in the internal factory bank are accessed via the host application's preset menu. The additional presets are copied to disk by the UAD installer and can be loaded using the Settings menu in the UAD Toolbar (see "Using UAD Powered Plug-Ins" in Chapter 7 of the UAD System Manual).

Preset Design Tips

Here are some practical tips for creating useful reverbs with DreamVerb. These are not rules of course, but techniques that can be helpful in designing the perfect sonic environment.

ER = Early Reflections	Hf = High frequency
LF = Late-field Reverberation	Lf = Low frequency

General Tips (a tour):

- Start by setting a general timing on the ER and LF graphs to give a rough reverb size. This timing ordinarily needs to be tweaked several times along the way.
- The materials and air density define the frequency decay of the LF, and also the coloration of the ER if ER filtering is used (the slider on the right of the Reflections panel).
- Typically, materials should be blended. Try blending contrasting high frequency roll-off materials with high-frequency reflecting materials or inverse materials. This tends to add nice dimension to the LF tail. Start with one useful material and experiment with blending.
- Materials can have an extreme filtering effect if no air density is used. Most presets sound better with an air blending. If you don't want the additional coloration of air, blend with "Ideal Gas" which performs no filtering.
- The room shapes define the ER pattern; they do not effect the LF. Solo the ER and choose a shape that works well for your source or environment.
- Blending shapes does not always yield desirable results. Use shape blending with discretion, or to define a more complex room.
- Start with the EQ flat, set the approximate sound with the materials, then EQ the input to cut or boost specific frequencies.

- The EQ is often most useful for a simple Lf or Hf roll-off/boost, or to notch out bothersome frequencies for particular sources. For full mix ambience/mastering presets, use the EQ to cut most of all LF input, which yields added ambience without mucking up the mix. This is a powerful EQ, so experiment!
- Try different diffusion settings for your preset (the slider on the right of the Reverberation panel). Diffusion radically alters the reverberation sound and is source dependent. Higher diffusion values yield a fuller sound, good for percussive sounds; lower diffusion values yield a less dense sound, good for vocals, synths, etcetera.
- When monitoring your preset, try switching from Dry solo, Wet solo, and a useful mix. Solo the reflections and reverberation, and disable/enable EQ. Try different sources and mixes. Reach for the headphones every now and then. In general just keep things moving, as ear fatigue can be particularly deceiving with reverb sounds.
- The Positioning panel is generally only needed for automation. Ignore these settings for preset design unless going for a panning effect or monitoring real-world use.
- Often when you've got a really great preset designed, all it takes are a few subtle changes to make a number of other great presets.

Tips for designing a natural environment sound:

- Make timing proportional. As the size of the simulated environment increases, the length of the pre-delay for the EF, LF, and LF tail should increase proportionally. Typically, ER and LF pre-delay should be not too far apart, with LF starting shortly after ER.
- Place the ER timing preceding/leading into the LF
- ER amplitude naturally decays. Slope the amplitude down from left to right.
- Use ER filtering, as this improves the reverb sound in almost all situations.
- Try a gradual Lf or Hf roll-off (or boost) with the EQ section. The left and right-most EQ bands are shelf filters, which are perfect for this job. The adjacent bands can be used to shape the roll-off.
- Try natural materials and air densities before the unnatural custom or inverse materials and air densities.
- Try adding onset (slope) to the LF, as many environments naturally have an LF onset.

• Read Chapter 44, "RealVerb Pro" (page 444) of this manual.

CHAPTER 11 Empirical Labs EL7 FATSO

Introduction

- FATSO Jr. Endorsed and scrutinized for accuracy by designer Dave Derr of Empirical Labs (originator of the hugely popular Distressor), UA has painstakingly recreated the highly regarded FATSO Jr. as a plug-in, capturing the sonic nuances of the hardware. The FATSO (Full Analog Tape Simulator and Optimizer) is designed to musically integrate frequencies and transients and increase the apparent volume of your source material in the same way classic analog equipment does. It achieves this through an ingenious design and a creative feature set, giving users the ability to impart the wonderfully warm and pleasing sonic characteristics of magnetic recording tape and class A transformer and tube circuits. The Input control gives the ability to dial in harmonic generation/distortion while "Tranny" and "Warmth" allow the user to dial in just the right amount of tape and tube tone. The FATSO also operates as a highly versatile compressor—useful for mixing and stereo buss compression. From tame to trashed, the FATSO offers a wide palette of possibilities for adding character and cohesiveness to your DAW tracks.
- **FATSO Sr.** Dubbed the FATSO Sr., UA has also worked closely with Dave Derr to bring you his never-before-available original concept of the FATSO, bundled at no additional charge. Adding his own custom mods that turn the original FATSO into an unbelievable powerhouse of tonal-shaping possibilities, the FATSO Sr. offers a "Tranny" saturation control, sidechain filtering, and deeper compression parameters including Threshold, Attack and Release. These special FATSO Sr. mods are only available with Universal Audio's plug-in version of this unique studio tool.

Note: The additional controls in the FATSO Sr. do not add to the DSP functionality of the FATSO Jr. Therefore, both plug-ins use the same amount of UAD DSP.

FATSO Screenshots

Figure 47. The FATSO Jr. plug-in window

Figure 48. The FATSO Sr. plug-in window

FATSO Functional Overview

Four Processing
TypesThe FATSO was essentially designed to integrate frequencies in a musical
manner and provide some foolproof vintage sounding compression. Gener-
ally, it is difficult to make the unit sound unnatural due to its vintage topology.
FATSO provides four types of processing.

Saturation and
Distortion
ProcessorHarmonic Generation & Soft ClipperBasically, this is a distortion generator associated with the Input knobs. Any-
time you pass a signal through the FATSO, it passes through this part except
in bypass. This processing is useful to softly but instantly clip peaks and tran-
sients, allowing a higher average level. Aggressive distortion can also be
achieved through the same controls.

It is well known that the triode distortion in tube circuits produces lots of 2nd order and 3rd order harmonics, in somewhat varying ratios. Analog tape also saturates in this manner. The 3rd order harmonic is induced in the FATSO by increasing the level through two discrete distortion circuits and is usually the result of flattening the tops and bottoms of waveforms. Second order harmonics are also added especially while compressing in the FATSO. The FATSO's input clipping will give you the same result. These lower order harmonics form "the octave" and "the octave and a fifth" to the fundamental musical tones. They are actually "musical" distortion. Harmonics above the 2nd and 3rd get increasingly harsh and unmusical, and therefore should be lower in amplitude (<-60 dB) to keep within our line of thinking. Second harmonic is considered to be the warmest and most "consonant" harmonic distortion.

Warmth Processor

High Frequency Saturation

This circuit is meant to simulate the softening of the high frequencies that occurs with analog tape. Basically, as the Warmth is increased, overly bright signals and transients will be quickly attenuated. The time constants are very nearly instant, so the high frequencies return very quickly after a loud burst.

The Warmth circuit is by far the most complex part of the FATSO. Basically, it is a very strange high frequency (HF) gain control circuit or HF limiter. It is very unobtrusive in operation since it gets in and out of the way very quickly. The desired result is akin to the HF saturation that analog tape exhibits when the HF amplitude interacts with the tape recorder bias to produce "self erasure" of certain frequencies. The nature of the filter allows the corner frequency to move as attenuation occurs.

There is only one control for Warmth but there are other ways to control the overall action of this circuit. If you do decide to use the compressor, set it up first because it affects the operation of Warmth. There is heavy interaction between the compressor and Warmth settings. Perhaps the best way to think of the settings is as compressor threshold, with 7 having the lowest threshold and the most Warmth, responding quickly and often to high frequency content. Just remember that instead of controlling the overall level, the Warmth "compressor" threshold only affects the high frequencies.

The Tranny Processor

Transformer & Tape Head Emulation

The Tranny circuit ("Tranny" is short for transformer) is a simulation of the effect of input and output transformers of older devices and adds the low frequency harmonics that characterize analog tape. This is extremely useful on pure low frequency type tones that don't cut through small speakers. It adds upper "warm" harmonics to frequencies below 150 Hz, especially those even lower such as 40 Hz, the low string on a bass guitar, helping it to cut through on smaller speakers. Transformer design and use is an art, and there are always trade-offs. However, it has been widely known that a good audio transformer circuit can do wonderful things to an audio signal. This was the goal of the Tranny circuit. The hardware designers tried to emulate the desirable characteristics of the good old input/output transformers in a consistent musical way, and in a selectable fashion. The addition of harmonics and peak saturation along with frequency and phase changes on the low frequencies occurs. They found that they could capture the low frequency effects of large and now expensive older output transformers in a weird, internally buffered switchable design.

To sum up the musical results of the Tranny circuit, there will be a little more edge in the midrange, and the super low frequencies will have been harmonically altered in a way that allows them to sound louder, even though the peaks are less than the original. Playback on small speakers will show an improved audibility of low end from the result of the psycho-acoustically-pleasing distortion the Tranny adds.

Compression Classic Knee Compression, Empirical Labs Style Processor

These are your typical automatic leveling devices that you find used on just about every instrument and vocal track, as well as on the overall buss. Only it's Empirical Labs compression – smooth and sweet, but in your face!

There are essentially four discrete compressors in the FATSO: Buss, General Purpose (G.P.), Tracking, and Spank. Switching modes simultaneously sets the compressor threshold, ratio, attack, and decay. This was done to provide an easy-to-set, yet versatile group of curves. The release curve of all types is logarithmic, meaning it lets off quickly at first and then slows. This release curve is a big part of the FATSO's compressor sound.

Note: Threshold, attack, and decay values can be modified in the FATSO Sr.

Buss

Buss mode (green LED) is a very gentle 2:1 type ratio with slow attack, fast release, and very soft knee. One to four dB of gain reduction is typical for this compressor type. Five or more dB of Buss compression is hitting it hard!

G.P.

General Purpose mode (yellow LED) is medium attack slow release type that sounds pretty invisible while able to maintain a consistent RMS level. The slow release will not pull things into your face unnaturally.

Tracking

Tracking mode (green and yellow LED) is an 1176 type compressor that is great for tracking instruments and vocals during the recording process or during mixdown.

Spank

Spank mode (red LED) is a radical limiter type compressor that was specifically designed to emulate the nice squeeze of the older SSL talkback compressors from the 70's & 80's, but with quite a bit of higher fidelity. Note that Spank's aggressive nature will tend to dominate when combined with any of the other modes.

FATSO Controls

General notes about FATSO controls are below, followed by a detailed description of each channel-specific control, the global controls, and the FATSO SR. controls.

Mono/Stereo
OperationThe FATSO is a two-channel device capable of running in stereo or
dual-mono modes. Controls for both channels can be linked for ease of stereo
operation when both channels require the same values (see "Link Controls" on
page 130), or unlinked when dual-mono operation is desired.

Each of the channel functions has its own separate group of controls (one set each for channels 1 and 2). Since the controls for each of the two channels are identical, they are detailed only once.

Note: When the FATSO is used in a mono-in/mono-out configuration, the channel 2 controls have no effect and the LINK parameters (page 130) are disabled.

Pushbuttons All FATSO pushbuttons are momentary. The value of the parameter increments by one step each time the button is clicked (holding the button down does not continue to increment the value). The value cycles to the beginning when the end of the range is reached. Clicking on the control LED indicators has no effect, with the exception of the LINK parameters (page 130).

Tip: Shift+click any pushbutton to decrement its value by one.

Channel Controls

Input

The Input knob defines the signal level going into the plug-in. Higher levels result in a more saturated signal. Levels above 0 VU provide dramatically higher distortion characteristics, especially when clipped (as indicated by the Pinned LED). See THD Indicators below.

When the compressor is active (see "Compressor Mode"

below), higher input values also result in more compression, as indicated by the gain reduction meters (page 128).

Note: This control has no effect when Bypass (page 129) is active.

THD Indicators

The Total Harmonic Distortion (THD) LED's provide some reference operating levels. The yellow "O VU" LED light indicates around 1% THD, and the red "Pinned" LED indicates 5% THD or more. These LED's are an excellent guide to where the user is in the "Grunge Department." You will find that the harmonic distortion is generally more obvious on overall mixes and complex programs. On individual instruments, sometimes 10% distortion sounds "fat" and "analog" and isn't heard as distortion at all.

Compressor Mode

The COMP button defines which compressor mode is active. See "Compression Processor" on page 125 for a description of the modes.

Spank mode can be combined with any of the other three modes for a total of seven available compressor modes.

Note: Generally speaking, the Input and compressor Mode controls should be set before the other FATSO processor settings, because of the high degree of interaction between the compressor and the other processors.

Mode LED's The three Mode LED's indicate the active mode. Refer to Table 12 on page 128 for each specific value. The compressor is inactive when all Mode LED's are off.

Table 12. Compressor Mode LED States

Compressor Mode LED State	Active Compressor Mode(s)
All Unlit	Compressor inactive
Green	Buss
Yellow	General Purpose (G.P.)
Green + Yellow	Tracking (most versatile ratio)
Red	Spank
Red + Green	Spank + Buss
Red + Yellow	Spank + General Purpose
Red + Green + Yellow	Spank + Tracking

GR Meter The Gain Reduction Meter displays the amount of gain reduction occurring within the FATSO compressor, expressed as negative dB values.

COMP -20 - 15 - 10 - 7 - 5 - 3 - 2 - 1 Ch1

Note: At extreme settings, the GR Meter may indicate gain reduction is occurring even when the compressor is disabled. This behavior is identical to the hardware unit.

Warmth

This button defines the Warmth amount. Warmth simulates the softening of the high frequencies that occurs with analog tape saturation (see "Warmth Processor" on page 124 for detailed Warmth description). Higher values increase the

Warmth, as indicated by the Warmth Meter.

Values of 1 to 7 are available. The current value is indicated by the arc of Warmth LED's. Warmth is off when all LED's are unlit.

Warmth Meter The Warmth Meter is a very accurate display of the amount of high frequency attenuation, as defined by the Warmth button. The meter shows the amount of HF gain reduction occurring at 20 kHz.

Note: At extreme settings, the Warmth Meter may indicate activity even when Warmth is disabled. This behavior is identical to the hardware unit.

Bypass/Tranny

This black button is a multifunction control. Clicking the button repeatedly cycles through Tranny, Bypass, and Tranny Off modes. The currently active mode is indicated by the adjacent LED's.

Tranny (green LED)

The Tranny processor is active in this mode (see "The Tranny Processor" on page 124 for a detailed description of this mode). The Tranny circuit adds frequency "rounding," low order clipping, intermodular distortion and transient clipping. On FATSO Sr., the Tranny amount can be set with the Tranny Level control (page 134).

Note: Disabling Tranny will yield a significant reduction in UAD DSP usage when DSP LoadLock is disabled. If DSP LoadLock is enabled (the default setting), disabling Tranny will not reduce DSP usage.

Tranny Off (red and green LED's off)

In this mode, the Tranny processor is inactive but the other processors are active. This mode requires less UAD DSP than when Tranny is active.

Bypass (red LED)

All FATSO controls and processing for the channel are inactive in this mode.

Note: UAD DSP load is not reduced in Bypass mode. If you want to reduce UAD DSP usage when bypassing both channels of the FATSO, use the Power switch instead (page 131).

Output

The Output knob controls the signal level that is output from the plug-in.

Note: This control has no effect when Bypass ("Bypass/Tranny" on page 129) is active.

Global Controls

The global controls are not channel-specific; they apply to both channels.

Link Compress The control signal sidechains of the gain reduction processors for channels 1 and 2 can be linked using the Link Compress function.

To activate Link Compress, click the LINK COMPRESS text or LED on Ch1, on the left. The feature is active when the LED is illuminated.

In typical use on stereo signals, Link Compress should be active so the stereo imaging is maintained. If the compressor is inactive ("Compressor Mode" on page 127), or when FATSO is used in a mono-in/mono-out configuration, this control has no effect.

Important: Unlike the other controls for channels 1 and 2, which are identical on the left and right sides of the interface, the Link COMPRESS function is on the left side only (not to be confused with Link CONTROLS, which is on the right side only).

Link Controls The parameter controls for channels 1 and 2 can be linked using the Link Controls function.

To activate Link Controls, click on the LINK CONTROLS text or LED on Ch2, on the right. The feature is active when the LED is illuminated.

Note: Although the left/right Warmth and Tranny controls are linked when Link Controls is active, the actual Warmth and Tranny processors are not stereo linked. This behavior is identical to the original hardware.

Controls Linked

Link Controls is provided for stereo operation when both channels require the same values. When enabled, the right channel controls "snap" to match the left channel control values, and modifying any channel control causes its stereo counterpart control to move to the same position (channel 1 & 2 controls are ganged together in this mode).

Important: Right channel parameter values are lost the moment Link Controls is enabled.

Controls Unlinked

Unlink the controls when dual-mono operation is desired. Channel 1 and 2 controls are completely independent in this mode, and automation data is written and read by each channel separately. Link Controls is disabled when the FATSO is used in a mono-in/mono-out configuration.

Important: Unlike the other controls for channels 1 and 2, which are identical on the left and right sides of the interface, the Link CONTROLS function is on the right side only (not to be confused with Link COMPRESS, which is on the left side only).

Power

The Power toggle switch determines whether the plug-in is active. It is useful for comparing the processed settings to the original signal. When Power is in the Off (down) position, plug-in processing is disabled, UAD DSP usage is reduced, and all LED's are unlit.

Note: UAD-2 DSP usage is reduced only when DSP LoadLock is disabled. If DSP LoadLock is enabled (the default setting), disabling Power will not reduce DSP usage.

Click the lower portion of the switch to disable the plug-in; click the upper portion to activate (or click+drag up/down on the switch).

FATSO Sr. Controls

These controls are unique to the FATSO Sr. However, because the additional controls in the FATSO Sr. do not add to the DSP functionality of the FATSO Jr., both plug-ins use the same amount of UAD DSP.

Threshold

This knob enables manual threshold control of the FATSO compressor. Higher values lower the threshold, and therefore increase the amount of compression. A value of 5 is the unity setting.

The Input control (page 127) also affects the compression threshold. Generally speaking, set the

amount of desired signal saturation with Input first, then adjust Threshold as desired.

Filter (HP SIDE FILT)

Filter regulates the cutoff frequency of the filter on the compressor's control signal sidechain. When active, frequencies below the filter value are not passed to the sidechain. Values of 60 Hz, 120 Hz, 240 Hz, 480 Hz, and Off are available. The filter slope is 6 dB per octave. When the compressor is disabled, Filter has no effect and its LED turns off. When the compressor is enabled, Filter returns to its original value.

Tip: Removing low frequency content from the sidechain can reduce excessive gain reduction and/or "pumping" on bass-heavy audio signals without reducing bass content of the audio signal itself.

Note: The Filter parameter affects the control signal (sidechain) of the compressor only. It does not filter the audio signal.

Attack

Attack sets the amount of time that must elapse once the input signal reaches the threshold level before compression is applied. The faster the attack, the more rapidly compression is applied to signals above the threshold.

ATTACK The available attack time values are 0.9ms, 10ms, 30ms, 60ms, and Default (unlit). The unlit behavior is depends upon whether or not the compressor is active. These behaviors are described below.

Note: Attack values are approximations. Actual attack and release times may vary depending on the compressor mode selected.

Attack LED's Unlit – Compressor Active

When the compressor is enabled and all Attack LED's are unlit, the attack characteristic of the active compressor mode in FATSO Jr. is used. This "default" FATSO Jr. behavior can then be manually overridden with the Attack button. However, when "pure" Spank mode is active, Attack cannot be modified. When Spank mode is combined with another compressor mode, Attack can be changed, but the results are typically very subtle.

Tip: After experimenting with other time constants, one can return to the default attack setting of the FATSO Jr. if desired by cycling the attack control until NO LEDs are lit (which indicates the default FATSO Jr. time constant).

Attack LED's Unlit – Compressor Inactive

When the compressor is disabled and all Attack LED's are unlit, the button is disabled.

Note: This control has no effect when the compressor is inactive, or when it is in "pure" Spank mode (see "Compressor Mode" on page 127).

Release

Release sets the amount of time it takes for compression to cease once the input signal drops below the threshold level. Slower release times can smooth the transition that occurs when the signal dips below the threshold, especially useful for material with frequent peaks. However, if you set too large of a Release time, compression for sections of audio with loud signals may extend to

lengthy sections of audio with lower signals.

The available release time values are 0.05s, 0.1s, 0.s, 0.5s, and Default (unlit). The unlit behavior is depends upon whether or not the compressor is active. These behaviors are described below.

Note: Release values are approximations. Actual attack and release times may vary depending on the compressor mode selected.

Release LED's Unlit – Compressor Active

When the compressor is enabled and all Release LED's are unlit, the release characteristic of the active compressor mode in FATSO Jr. is used. This "default" FATSO Jr. behavior can then be manually overridden with the Release button. However, when "pure" Spank mode is active, Release cannot be modified. When Spank mode is combined with another compressor mode, Release can be changed, but the results are typically very subtle.

Tip: After experimenting with other time constants, one can return to the default release setting of the FATSO Jr. if desired by cycling the release control until NO LEDs are lit (which indicates the default FATSO Jr. time constant).

Release LED's Unlit – Compressor Inactive

When the compressor is disabled and all Release LED's are unlit, the button is disabled.

Note: This control has no effect when the compressor is inactive, or when it is in "pure" Spank mode (see "Compressor Mode" on page 127).

Tranny Level

This control determines the amount of Tranny processing (see "The Tranny Processor" on page 124 for a detailed description). Higher values make the Tranny effect more prominent. Increasing the Tranny level also increases the signal THD (see "THD Indicators" on page 127), and the sensitivity of the Warmth processor (page 128). A value of 5 is the unity setting.

Note: This control has no effect when the Tranny processor is inactive (see "Bypass/Tranny" on page 129).

- LF Sat LED The LF Sat (Low Frequency Saturation) LED indicates the amount of LF saturation in the Tranny processor. Higher Tranny Level values increase the LF saturation.
- FATSO Jr.When loading presets created on the FATSO Jr. into the FATSO Sr., the parametersPresetsrameters that are unique to FATSO Sr. are set to their default control values.
The default values of the unique FATSO Sr. parameters are: Thresh-
old/Tranny knobs at 5, and Filter/Attack/Release buttons off.

The Empirical Labs EL7 FATSO Jr. hardware unit

All visual and aural references to the FATSO and all use of EMPIRICAL LABS's trademarks are being made with written permission from EMPIRICAL LABS. Special thanks to Dave Derr for assistance with this project.

EMT 140 Plate Reverb

Overview

EMT's founder Wilhelm Franz made a breakthrough in 1957 with the release of the EMT 140, which utilized a resonating metal plate to create ambience. Nothing is quite like the wonderfully lush and distinctive tone of plate reverb that still endures as part of the fabric of modern music. However, plate reverb systems are large, expensive, require maintenance, and need to be isolated from external vibration; therefore plates are usually found only in commercial studios.

Universal Audio's uncanny representation of that unmistakable sound can be found in the EMT 140 plug-in. Measured and analyzed by UA's DSP circuit modeling experts and then tuned by ear over a four month period, the EMT 140 replicates the sonic signature of three uniquely different EMT 140s formerly installed at the Plant Studios in Sausalito, CA. That's nearly two thousand pounds of sound in one plug-in! Impractical or impossible for most before, Universal Audio brings this classic mix tool within the reach of everyone. Licensed and endorsed by EMT Studiotechnik GmbH as the world's only authentic plate reverb emulation.

We thoughtfully combined the look of various elements from the EMT 140 system into one convenient panel, replicating the original damper controls for decay, and adding additional controls for the convenience of the modern DAW user.

EMT 140 Screenshot

Figure 49. The UAD EMT 140 plug-in window

EMT 140 Controls

The EMT 140 interface is an amalgam of controls found at the plate amplifier itself and the remote damper controls, plus a few DAW-friendly controls that we added for your convenience. The GUI incorporates the original look and feel of those controls, and utilizes that look for the DAW-only controls.

Note: When adjusting parameters, keyboard shortcuts are available for fine, coarse, and other control methods. See "Shortcuts" in Chapter 7 of the UAD System Manual for details.

Input Filter The Input Filter is a dedicated equalizer that is used to reduce low frequency content in the reverb. On hardware plate systems, this setting is rarely modified because it is found at the plate amplifier unit itself and is not easily accessed from the control room.

> EMT 140 contains two types of filters: original EMT electronics and Martech electronics which was/is a common plate system retrofit.

In the modeled source units at The Plant, plates A and B use the EMT electronics while Plate C utilizes the Martech electronics. In EMT 140, you can use either filter type with any of the three available plates.

The original EMT filter (indicated by black text) is a cut filter centered at 80 Hz, with three available levels of attenua-

tion: -4 dB, -10 dB, and -16 dB. In controls mode, these values are prefaced with an "E" to designate the original EMT electronics model.

The Martech filter (indicated by red text) is a shelf filter, therefore all frequencies below the frequency are reduced. Six shelving frequencies are available: 90 Hz, 125 Hz, 180 Hz, 250 Hz, 270 Hz, and 360 Hz. In controls mode, these values are prefaced with an "M" to designate the aftermarket Martech electronics model.

Note: There is one Input Filter per plug-in instance. Each plate model (A, B, C) within a preset cannot have a unique Input Filter value.

Reverb Controls

Plate reverb systems are extremely simple: A remote damper setting, and a high pass or shelf filter found at the plate itself. Additional manipulation is often used, including reverb return equalization, which is typically achieved at the console. Predelay is/was often achieved when necessary with tape delay, sending the return to a tape deck. Different tape speeds allowed different pre-delay amount.

The original damper controls are remote control devices, usually found somewhere near the control room for quick access. Our hybrid panel combines three remotes into the panel, with a switch to select each of the three available systems.

Note: The reverb controls (Plate Select and Reverb Time) are completely independent from all other plug-in controls.

Plate Select

Three plate models (algorithms) are available for reverb processing. This switch specifies which plate will be active.

Each setting is a model of a completely separate and unique plate system. Three 140's for the price of one!

Note: You can also switch the active plate by clicking the A, B, or C letters above the Plate Select switch and the Reverb Time meters.

Reverb Time Meters The Reverb Time Meters display the reverb time of plates A, B, and C in seconds. The meter for the active plate model (as specified by the Plate Select switch) is illuminated.

Damper Controls (Reverb Time)

The Damper Controls (the buttons beneath the Reverb Time Meters) change the reverb time for each plate. The range is from 0.5 to 5.5 seconds, in intervals of 0.1 sec. Click the buttons to increment or decrement the reverb time.

Note: The reverb time can be changed by dragging a Reverb Time Meter "needle" in addition to its corresponding Damper controls.

Stereo Controls

Width

Width allows you to narrow the stereo image of EMT 140. The range is from 0 – 100%. At a value of zero, EMT 140 returns a monophonic reverb. At 100%, the stereo reverb field is as wide as possible.

Balance

This control balances the level between the left and right channels of the reverb return. Rotating the knob to the left attenuates the right channel, and vice versa (it is not a mono pan control).

EQ Controls

This group of parameters contains the controls for EMT 140's onboard utility equalizer. It is a two band (low and high) shelving EQ that uses analog-sounding algorithms for great tonal shaping options.

The EQ section is independent from the reverb algorithms and the Input Filter on the modeled plate systems. See "Input Filter" on page 136.

The frequency parameters specify the center of the transition band, which is defined as the frequency at which the level in dB is the midpoint between DC and the band edge level.

Note: There is one EQ per plug-in instance. Each plate model (A, B, C) within a preset cannot have unique EQ values.

- **EQ Enable** The EMT 140 equalizer can be disabled with the EQ Enable switch. UAD DSP usage is not increased when EQ is enabled.
- **Low Frequency** This parameter specifies the low shelving band transition frequency to be boosted or attenuated by the low band Gain setting. The range is 20 Hz to 2 kHz.

Because this is a shelving EQ, all frequencies below this setting will be affected by the low band Gain value. Low Gain This parameter determines the amount by which the transition frequency setting for the low band is boosted or attenuated. The available range is ± 12 dB, in increments of 0.5 dB (fine control) or 1.0 dB (coarse control). **High Frequency** This parameter determines the high shelving band transition frequency to be boosted or attenuated by the high band Gain setting. The range is 200 Hz to 20 kHz. Because this is a shelving EQ, all frequencies above this setting will be affected by the high band Gain value. **High Gain** This parameter determines the amount by which the frequency setting for the high band is boosted or attenuated. The available range is ± 12 dB, in increments of 0.5 dB (fine control) or 1.0 dB (coarse control).

Modulation Controls

The EMT 140 reverb time can be modulated by a low frequency oscillator using rate and depth controls. The effect is subtle but it can increase dispersion and reduce ringing on some source material, such as loud signals with sudden endings and percussive content.

Mod Rate

Mod Rate controls the rate of reverb time modulation. The available range is from 0.01 Hz to 1.0 Hz.

Mod Depth

This parameter controls the amount of reverb time modulation. The available range is from 0 - 10 cents.

Output Meter

The vintage-style VU Meter represents the plug-in output level. It is active when the Power switch is on, and slowly returns to zero when Power is switched off.

Blend Controls

Predelay

The amount of time between the dry signal and the onset of the reverb is controlled with this knob. The range is 0.0 to 250 milliseconds.

This control uses a logarithmic scale to provide increased resolution when selecting lower values. When the knob is in the 12 o'clock position, the value is 50 milliseconds.

Mix

The Mix control determines the balance between the original and the processed signal. The range is from Dry (0%, unprocessed) to Wet (100%, processed signal only).

This control uses a logarithmic scale to provide increased resolution when selecting lower values. When the knob is in the 12 o'clock position, the value is 15%.

Note: If Wet Solo is active, adjusting this knob will have no affect.

Wet Solo

The Wet Solo button puts EMT 140 into "100% Wet" mode. When Wet Solo is on, it is the equivalent of setting the Mix knob value to 100% wet (and the Mix value is ignored).

Wet Solo defaults to On, which is optimal when using EMT 140 in the "classic" reverb configuration (placed on an effect group/bus that is configured for use with channel sends). When EMT 140 is used on a channel insert, this control should be deactivated.

Note: Wet Solo is a global (per EMT 140 plug-in instance) control.

Power Switch

This toggle switch enables or disables EMT 140. You can use it to compare the processed settings to the original signal, or to bypass the plug-in which reduces (but not eliminates) the UAD DSP load (unless UAD-2 DSP LoadLock is enabled). The red EMT power indicator glows brighter when the plug-in is enabled.

Note: The EMT 140 distills 1800+ pounds of classic vintage reverb into a single plug-in. Exercise caution when lifting.

CHAPTER 13 EMT 250 Electronic Reverberator

Introduction

Unveiled by EMT at the AES convention in 1976 and inducted into the TEC Hall of Fame in 2007, the EMT 250 was the first digital reverberation device to create ambience through a purely electronic system. With its single reverb program and iconic lever-driven control surface, the EMT 250 is still an indispensable tool within the record-making elite and is widely considered one of the best-sounding reverbs ever made. Although only around 250 were built, the EMT 250 has made an immeasurable impact on record making history in the hands of studio legends like George Massenburg, Bruce Swedien, Allen Sides and many others. Captured from Allen Sides' unit at Ocean Way Recording, endorsed by EMT 250 creator Dr. Barry Blesser from his original documentation, the UAD version of the EMT 250 goes beyond emulation and is the very same algorithm found in the original units—for a fraction of its original \$25,000 price!

Besides the coveted reverb program, the EMT 250 for UAD provides the five additional effects (Delay, Phasing, Chorus, Echo and Space) also included in the original unit. Lighted pushbuttons select the desired program, while four click-stop levers provide the primary reverb parameters of delay time, predelay, and high and low Filtering. LED ladders provide additional visual reinforcement of program selection and parameter positioning. Like the hardware, the plug-in operates in "quad," with two discrete stereo output pairs accessed through the added front/rear output switch. Additional "digital only" features include dry/wet mix, wet solo, reduced noise (if desired), and hard bypass via the EMT power icon.

EMT 250 Screenshot

Figure 50. The EMT 250 plug-in window

Functional Overview

Program Modes The EMT 250 offers six effect types: Reverb, Delay, Phase, Chorus, Echo, and Space. These effects are called "program modes" in the EMT 250. Only one mode can be active at a time.

Each program mode has up to five parameters that can be modified by the four main control "levers" plus the front/rear switch. The function of these controls varies per program mode (see below). Additionally, there are several global controls that have the same function in all modes.

Variable ControlThe function of control levers 1, 2, 3, and the Front/Rear switch depends
upon which program mode is active. This is a primary consideration to re-
member when operating the EMT 250. Table 13 on page 146 details the
varying functions of the control levers and the front/rear switch in each mode.

Important: The function of the "levers" and the front/rear switch changes depending on the program mode.

Each unique parameter in the plug-in retains a distinct value, but only the parameters that are active in the current program mode are visible in the graphical user interface. All parameters are always visible in Controls View (see Chapter 7 of the UAD System Manual), even when they are not active in the current program mode.

Important: The value of lever parameters that are not active in the current program mode are not saved in sessions or presets. The unsaved parameters are marked with an asterisk in Table 13 on page 146.

When switching between program modes that have different parameters mapped to the same control, parameter values are retained within each mode (controls jump back to the prior value that was set in each respective mode).

Lever 4 Predelay In all program modes, lever 4 controls the predelay (the initial delay before other processing occurs) of both channels (left and right). Predelay times of Oms, 20ms, 40ms, and 60ms are available in 4 steps. The green LEDs on the right side of lever 4 display the current predelay value.

Mono/Stereo Operation The EMT 250 hardware unit has one (mono) input. For accurate emulation when the plug-in is used in a stereo-in/stereo-out configuration, stereo signals at the plug-in input are summed to mono before processing; the dry signal is passed in stereo.

Four channels of processed audio, selectable with the Front/Rear Outputs switch, are generated from this mono input in all modes (with the exception of Echo, which has mono output only).

Front/Rear Outputs The EMT 250 hardware unit has four discrete outputs. Two outputs were designed to be used as the main stereo left/right outputs, or the "front" left/right outs in quadraphonic applications. The other two outputs were used for the "rear" left/right signals in quad (or other creative applications). The UAD EMT 250 fully models the individual sonics of all four outputs.

The name of the "Front/Rear Outputs" switch is derived from the original hardware design. This control (which is unique to the plug-in) enables access to the processed quadraphonic signal in pairs, at either the front L/R or rear L/R outputs. When a different sound is available at the front and rear outputs, the yellow "LED ring" around the control is illuminated. For program modes that do not offer quadraphonic processing (e.g., Delay), the switch is re-purposed to sum the processed outputs to mono. In Echo mode, it functions as an input mute.
In some program modes, the yellow "LED ring" around the control is illuminated to indicate that changing the switch position will change the sound. For program modes that do not offer quadraphonic processing (e.g., Delay), the switch is re-purposed to sum the processed outputs to mono. In Echo mode, it functions as an input mute.

Automation Some EMT 250 control functions change depending on the active mode (see "Variable Control Functions" on page 143 and Table 13 below). To accommodate this design, all EMT 250 parameters are exposed for automation and external control surfaces even if the parameter is not active in the current program mode.

Important: Parameters that are automated and/or externally controlled will have no effect if those parameters are not active in the current program mode.

- **Modeled I/O** All input and output characteristics of the EMT 250 are fully emulated in the plug-in. This includes all of its idiosyncrasies, such as the A/D and D/A anti-aliasing filters (which are not linear-phase), system latency, input clipping, and limited frequency response. All these quirks embellish the unique sonic signature.
- **EMT 250** Latency The EMT 250's anti-aliasing filters for its A/D and D/A conversion are not linear-phase filters; therefore our emulation does not have a latency that is the same at all frequencies. Thus, we cannot report to the delay compensation engines a delay that is correct for all frequencies. The value we report is good at low frequencies, but becomes off at high frequencies.

For example, when the plug-in is in Delay program mode and set with zero delay time and predelay values, the plug-in output will not be completely cancelled when mixing with flipped phase against an unprocessed track; high frequencies will leak through. However, the latency through the dry side of the wet/dry mix, and the latency when the plugin is bypassed via the EMT 250 Power switch (page 153), do not have this issue and will be fully compensated by the DAW.

See "Upsampled Plug-Ins" on page 563 for more information.

Program Mode Controls

The details of each unique program mode are below, followed by descriptions of the global controls, which affect all program modes.

Control Functions Table 13 displays the parameter that each control is mapped to for each of the EMT 250 program modes. See "Variable Control Functions" on page 143 for details.

Program Mode	Lever 1	Lever 2	Lever 3	Lever 4	Front/Rear
Reverb	Reverb Decay	LF Decay	HF Decay (damping)	Predelay	Output Pair
Delay	Coarse Delay Time	Fine Delay Time	Selects L/R channel for time adjustment*	Predelay	Stereo/Mono
Phase	Phase (curve)	(none)*	(none)*	Predelay	Output Pair
Chorus	(none)*	(none)*	Variation	Predelay	Stereo/Mono
Echo	Coarse Delay Time	Fine Delay Time	HF Decay (damping)	Predelay	Input Mute
Space	(none)*	(none)*	(none)*	Predelay	Output Pair
*Note: The parameter values of lever positions marked with an asterisk are not saved in sessions or presets.					

Table 13. The variable control functions of the EMT 250

Program Mode The Program Mode buttons define which of the available program modes is active. The six program modes are: Reverb (REV), Delay (DEL), Phase (PHAS), Chorus (CHOR), Echo, and Space (SPC).

Click a Mode button to activate that program mode; the button is illuminated for the currently active mode (only one mode can be active at a time). Each program mode and its associated parameters are described in detail below.

Tip: See Table 13 on page 146 for a matrix of controls that are available in each program mode.

Reverb Reverb program mode offers the same all-time classic reverb algorithm that made the EMT 250 famous.

Decay Time (Lever 1)

Lever 1 controls the main reverb tail decay time. The red LEDs on the left side of lever 1 indicate the current decay time; the green LEDs on the right side of lever 1 are inactive.

The decay time range (at 1 kHz) is 0.4s to 4.5s, selectable via 16 steps.

LF Decay (Lever 2)

Lever 2 controls the low frequency decay time (at 300 Hz). The red LEDs on the left side of lever 2 display the current value; the green LEDs on the right side of lever 2 are inactive.

Four multipliers are available: x 0.5, x 1.0, x 1.5, and x 2.0. The multiplier refers to a factor of the main decay time (lever 1). Higher values (upper lever positions) generally result in more low frequency content in the reverb tail.

HF Decay (Lever 3)

Lever 3 controls the high frequency decay time. The red LEDs on the left side of lever 3 display the current value; the green LEDs on the right side of lever 3 are inactive.

Four multipliers (at 6 kHz) are available: x 0.25, x 0.33, x 0.5, and max. At the max position, the HF decay factor is x 1.0 at approximately three seconds. The multiplier refers to a factor of the main decay time (lever 1). Higher values (upper lever positions) generally result in more high frequency content in the reverb tail.

Predelay (Lever 4)

Lever 4 is used as a typical reverb predelay parameter. See "Lever 4 Predelay" on page 144 for more information.

Front/Rear

In Reverb mode, the Front/Rear Outputs switch is illuminated. Changing the switch setting will yield a slightly different effect. See "Front/Rear Outputs" on page 144 for more information.

Delay Delay program mode offers two independent delay processors, one each for the left and right output channels. Up to 375ms delay time is available for each channel. Delay repeats (feedback) are not available in Delay mode; use Echo mode if delay feedback is desired.

Note: The maximum per-channel delay time of 375ms in Delay mode is obtained by setting the coarse, fine, and predelay times to their respective maximum values.

Coarse Delay Time (Lever 1)

Lever 1 controls the coarse delay time for the currently selected channel (left or right). The currently selected channel is defined by lever 3.

The coarse delay time range is 0 to 300ms, selectable via 16 steps. The green LEDs on the right side of lever 1 display the current value; the red LEDs on the left side of lever 1 are inactive.

Fine Delay Time (Lever 2)

Lever 2 controls the fine delay time for the currently selected channel (left or right). The currently selected channel is defined by lever 3.

Fine delay times of Oms, 5ms, 10ms, and 15ms are available. The green LEDs on the right side of lever 2 display the current value; the red LEDs on the left side of lever 2 are inactive.

Note: Levers 1 and 2 both control the delay time, but these parameters are not individually exposed for external control surfaces and automation. Instead, a single delay time parameter is exposed for each channel, and levers 1 and 2 in the plug-in interface are both updated to match the value.

Channel Select (Lever 3)

In Delay mode, lever 3 selects which channel (left or right) the delay time parameters (levers 1 and 2) will affect. When lever 3 is in position "L" the left channel delay time can be adjusted; when in position "R" the right channel delay time can be adjusted.

The green LEDs on the right side of lever 3 display the channel selected for delay time adjustment; the red LEDs on the left side of lever 3 are inactive.

Note: Lever 3 position "I" is a duplicate of position "II – L" in Delay mode. Likewise, position "IV" is a duplicate of position "III – R." All positions can be used to select a channel for delay time adjustment. **Important:** In Delay mode, lever 3 does not control a "real" parameter; it is only used to select the active channel for other parameters in the graphical user interface. For this reason, the parameter is not exposed for external control surfaces or automation, nor is it saved in sessions or presets.

Predelay (Lever 4)

Lever 4 can be used as a common predelay to both channels (the predelay time is added to the delay times of both channels). See "Lever 4 Predelay" on page 144 for more information.

Front/Rear

In Delay mode, the Front/Rear Outputs switch is not illuminated (the sound is identical in both pairs of outputs). When moved to the Rear position, the plug-in output is summed to mono. See "Front/Rear Outputs" on page 144 for more information.

Phase Phase program mode creates a comb filter curve that results from the addition and subtraction of two signals with a small time shift between them. The comb filter changes the amplitude of the source signal's harmonic overtones, resulting in interesting tonal variations.

Tip: Phasing is most apparent when the plug-in is set to 100% wet (or when Wet Solo (page 154) is active).

In the EMT 250, the input is fed to two delay processors; one with a fixed delay time of 15ms, and the other which is variable from 0–15ms, controlled by lever 1. By changing this variable "time shift" the phase (shape) of the comb filter, and therefore the timbre of the output signal, is changed.

Note: Unlike many "phasors," the EMT 250 does not modulate the variable "time shift" with a low frequency oscillator (LFO), which results in the continuously varying "swooshing" effect that is often associated with the process name. This conventional "phasor effect" can be reproduced (with outstanding results) by moving lever 1 back and forth, either manually or with automation.

Phase (Lever 1)

In Phase program mode, lever 1 controls the delay time (the phase "time shift") between the two signals that create the comb filter. Phase values of Oms to 15ms are available, selectable via 16 steps.

In Phase mode the green LEDs to the of right lever 1 are active, but the panel markings (0–300ms) do not represent the actual phase delay time values. Instead, the LEDs indicate the relative value between 0–15ms.

Predelay (Lever 4)

Lever 4 can be used as a common predelay to both phase delays. See "Lever 4 Predelay" on page 144 for more information.

Note: Levers 2 and 3 have no effect in Phase program mode.

Front/Rear

The Front/Rear Outputs switch is illuminated in Phase program mode. Changing the switch setting will yield a different comb filter phase. Due to the nature of the effect in Phase mode, when the switch is in the Rear position and the Phase time (lever 1) is at minimum and maximum values, the signal is only output on one side (right-only at minimum, left-only at maximum). This behavior is identical to the original hardware. See "Front/Rear Outputs" on page 144 for more information.

For more information about phasing, see the "Flangers and Phasors" article in our December 2008 Webzine:

• http://www.uaudio.com/webzine/2008/december/doctors.html

Chorus Chorus program mode creates an "ensemble" effect by simulating the impression of multiple imprecisions added to the original signal. In EMT 250, this is accomplished by routing the same signal to four delay processors, each having short delay times that are continuously and randomly modulated.

While it was necessary to combine the various physical outputs for variations of Chorus complexity, the EMT 250 plug-in is "pre-mixed" in four popular combinations.

Note: Levers 1 and 2 have no effect in Chorus program mode.

Chorus Mode (Lever 3)

Four subtle variations of the chorus effect are available (I, II, III, and IV). Lever 3 specifies the current variation.

Positions "I" and "II" are of a simpler nature, while "III" and "IV" are more complex. Position "I" duplicates the Left Front and Right Front outputs of the hardware. "II" duplicates Left Rear and Right Rear outputs of the hardware. "III" combines both the Left Front and Left Rear on the left side, and Right Front and Right Rear on the right. "IV" combines Left Front, Left Rear and Right Rear on the left side, and Left Rear, Right Front and a phase inverted Right Rear on the right. "IV" imparts a pseudo-quadraphonic sound.

Predelay (Lever 4)

Lever 4 is can be used as a common predelay to all four delays. See "Lever 4 Predelay" on page 144 for more information.

Front/Rear

In Chorus mode, the Front/Rear Outputs switch is not illuminated (the sound is identical in both pairs of outputs). When moved to the Rear position, the plug-in output is summed to mono. See "Front/Rear Outputs" on page 144 for more information.

Echo Echo program mode produces a single monophonic delay effect, with feedback and adjustable delay time. Up to 375ms of delay is available.

> The feedback (recirculation) circuit is always active in Echo mode. The feedback signal path is attenuated by approximately 10% per loop circulation, and includes an adjustable high frequency attenuator for damping.

> **Note:** The maximum delay time of 375ms in Echo mode is obtained by setting the coarse, fine, and predelay times to their respective maximum values.

Coarse Echo Time (Lever 1)

Lever 1 controls the coarse delay time. The coarse delay time range is 0 to 300ms, selectable via 16 steps.

The green LEDs on right side of lever 1 display the current value; the red LEDs on the left side of lever 1 are inactive.

Fine Echo Time (Lever 2)

Lever 2 controls the fine delay time. Fine delay times of Oms, 5ms, 10ms, and 15ms are available. The green LEDs on right side of lever 2 display the current value; the red LEDs on the left side of lever 2 are inactive.

Note: Levers 1 and 2 both control the echo time, but these parameters are not individually exposed for external control surfaces and automation. Instead, a single echo time parameter is exposed, and levers 1 and 2 in the plug-in interface are both updated to match the value.

HF Decay (Lever 3)

Lever 3 controls the high frequency damping in Echo mode. The red LEDs on left side of lever 3 display the current value; the green LEDs on the right side of lever 3 are inactive.

Four multipliers are available: x 0.25, x 0.33, x 0.5, and max. Higher values (upper lever positions) result in more feedback.

Predelay (Lever 4)

Lever 4 is used as a predelay to the echo processor in this mode. The predelay time is added to the echo times, but not to the HF decay feedback loop. See "Lever 4 Predelay" on page 144 for more information.

Front/Rear

The Front/Rear Outputs switch is not illuminated in Echo mode (the same monophonic signal is generated at the front and rear outputs). However, the Front/Rear Outputs switch has a special function in Echo mode.

In the Front position, the program behaves normally. In the Rear position, the input to the echo processor is muted, while still allowing the echo output to be passed. This feature is useful for adding echo to specific passages only, by flipping the switch to Front when echo is desired. The behavior is identical to the popular "dub" switch on the Roland RE-201 ("Echo/Normal" on page 470). See "Front/Rear Outputs" on page 144 for more information.

Space Space mode is a special reverb program with an extremely long decay time and linear distribution of the reverberation time with frequency (all frequencies decay at the same rate). Because this condition doesn't exist in nature, and the program was originally intended for science fiction productions, the "reverberation in outer space" moniker was derived.

The reverb decay time is approximately 10 seconds in Space mode. Predelay and Front/Rear are the only adjustable parameters in this program mode.

Note: Levers 1, 2, and 3 have no effect in Space mode.

Predelay (Lever 4)

Lever 4 is used as a typical reverb predelay parameter. See "Lever 4 Predelay" on page 144 for more information.

Front/Rear

In Space mode, the Front/Rear Outputs switch is illuminated. Changing the switch setting will yield a slightly different effect. See "Front/Rear Outputs" on page 144 for more information.

Global Controls

The global controls are not program-specific; they apply to all program modes.

Power

The Power button (the red EMT logo) determines whether the plug-in is active. It is useful for comparing the processed signal to the original signal. Click the button to disable the plug-in; click it again to enable it.

When Power is in the Off (unlit) position, plug-in processing is disabled, and UAD DSP usage is reduced.

Note: UAD-2 DSP usage is reduced only when DSP LoadLock is disabled. If DSP LoadLock is enabled (the default setting), disabling Power will not reduce DSP usage.

Input Meter The Input Meter indicates the level going into the plug-in. On the original hardware, the red "Register" LED illuminates when digital full code is reached, at 6 dB above 0 dB (i.e., there is 6 dB of headroom on the hardware, as the meaning of "0 dB digital" wasn't yet standardized in those days).

The distortion characteristics of the A/D converters are modeled, therefore "EMT 250-style" clipping can be heard when the EMT 250 input is overdriven.

Dry/Wet

The Dry/Wet slider control determines the balance between the original and the processed signal. The range is from 0% (dry, unprocessed) to 100% (wet, processed signal only).

This control uses a logarithmic scale to provide increased resolution when selecting lower values. When the slider is in the center position, the value is 15%.

Note: If Wet Solo is active, adjusting Dry/Wet will have no effect.

Wet Solo The Wet Solo button puts the EMT 250 into "100% Wet" mode. When Wet Solo is on, it is the equivalent of setting the Dry/Wet control to 100% wet.

Wet Solo defaults to On, which is optimal when using the EMT 250 in the "classic" reverb configuration (placed on an effect group/buss that is configured for use with channel sends). When the EMT 250 is used on a channel insert, this control should be deactivated.

Note: Wet Solo is a global (per EMT 250 plug-in instance) control.

Noise

When Noise is active, the noise characteristics of the original hardware unit are fully intact. Disabling Noise eliminates the modeled noise characteristics for quieter operation.

Noise is active when the yellow LED is illuminated; it is enabled by default. Click the LED to change the setting.

The Noise parameter is unique to the UAD EMT 250 plug-in. Noise is dynamic to the response of the effect processing, and the noise level differs from program to program. The noise floor of the hardware EMT 250 may seem a bit high when compared to modern digital processors, but it adds to the EMT 250's quirky character.

CHAPTER 14 EP-34 Classic Tape Echo

EP-34 Overview

The EP-34 combines EP-3 and EP-4 sonics and features to achieve the best of the later solid-state Echoplex* designs. The Echoplex uses an infinite tape loop combined with a sliding record head that allows the user to achieve the desired delay length. EP-34 emulates the great idiosyncrasies of these tape-based echo units such as the unique Echo Delay record head slider that can be moved in real-time while used in conjunction with the Echoplex's Echo Repeats control to create echo and pitch chaos. The distinct and musical input clipping is captured in the units' Record Volume control making the EP-34 a tone box for distortion. Echo Volume allows the blending of the original and effected signal, however even the dry signal is affected by the unit. The Echoplex self-oscillation capabilities are captured as well, including the "squelch" effect (an interruption in self-oscillation) achieved at extreme settings when processing low-frequency material like drum loops with heavy kick drum. All this makes the EP-34 more than just a delay, but an instrument that can be played by manipulating the controls while in chaotic oscillation. Just like the hardware, faster-than-tape-path speeds can also be achieved, leading to 'sonic-boom/tape squeal' effects again adding to chaotic but musical attributes of the original hardware. The EP-34 also has other warts-and-all artifacts of tape such as self-chorusing due to speed variations caused by random friction in the tape path plus pinch roller wow and flutter. The EP-34 includes the metering and unusual but uniquely musical tone controls found on the EP-4, but removes its undesirable in-line noise reduction circuit that users often electronically disabled (Maestro removed this circuit soon after the product's release).

"Extras" not found on the original hardware include Tempo Sync, Input Select (allows for a cleaner sound [LO] or a dirtier sound [HI]), Tension (the Echoplex has an adjustable tension nut underneath the delay time slider for a snappy or sludgy response time), Echo Send (identical in function to RE-201 "dub switch"), Wet Solo, Pan (wet signal only), and Power (plug-in bypass).

^{*}EP-34 Tape Echo is not affiliated with, sponsored nor endorsed by any companies currently using the Echoplex name. The EP-34 Tape Echo name, as well as the EP-3 and EP-4 model names, are used solely to identify the classic effects emulated by Universal Audio's product.

EP-34 Tape Echo Screenshot

Figure 51. The UAD EP-34 Tape Echo plug-in window

EP-34 Controls

Echo Delay Echo Delay controls the delay time of the unit. The selected value is shown in the Echo display (page 157).

The parameter can be adjusted by using the metallic "slider handle" or the "slider nose" (both sliders control the same parameter; see Figure 52).

Figure 52. The Echo Delay sliders

The available delay range is 80 to 700 milliseconds. When Sync is active, beat values from 1/64 to 1/2 can be selected.

When the beat value is out of range, the value is displayed in parenthesis. This occurs in Sync mode when the time of the note value exceeds 700ms (as defined by the current tempo of the host application). See Chapter 8 in the UAD System Manual for more information about tempo synchronization.

Tip: Click the control slider(s) then use the computer keyboard arrow keys to increment/decrement the sync value.

Echo Display

This "window" displays the current delay time of the EP-34. Displayed values are defined by the Echo Delay parameter (page 156). Delay values can be entered here directly using

the text entry method.

When Sync mode is off, delay times are expressed in milliseconds. When Sync is on, delay times are expressed as a fractional bar value.

When the beat value is out of range, the value is displayed in parentheses. This occurs in Sync mode when the time of the note value exceeds 700ms (as defined by the current tempo of the host application).

Echo Repeats

This knob controls the repeat level (feedback) of the echo signal. At the minimum (fully counter-clockwise) position, only one repeat is heard. Rotating the control clockwise increases the number of echoes. Higher values will cause self-oscillation.

The self-oscillation of the EP-34 is one of the magic features that really makes it more than a mixing tool, it's also an instrument

to be played. The effect may be used subtly, sending the unit into gentle oscillation on held notes, or can be put into "over the top" oscillation with extreme settings.

The EP-34's oscillation qualities are heavily dependent upon program material and control settings. Different sources of audio, gain, tone, repeat rate and input settings will all effect "oscillation performance." The EP-34 can also achieve oscillation with no signal, making the it a truly unique instrument.

Echo Volume

This knob determines the wet/dry mix of the delayed signal. In the minimum position, the "dry" signal is colored by the circuitry of the modeled emulation. Rotate the control clockwise for louder echo. Reducing the control to its minimum value will mute the delay.

The EP-34 models the unusual taper of this control that is found on the original hardware. It is normal operation to have the control in the 85–95% range to get a "50/50" wet/dry balance.

Note: When the Wet switch (page 160) is in the On position, Echo Volume has no effect.

Recording Volume Recording Volume adjusts the input gain and clipping characteristics of the delayed tape signal. Increasing this control will increase the tape distortion and "grit" that is an important element of the famous hardware sound. The Recording Volume is indicated by the Input Meter.

Input Meter

The Input Meter in the EP-34 is a three-segment horizontal LED array (two green, one red) that indicates the recording level at the input of the tape recorder.

The yellow LED indicates that the plug-in is active. When the Power switch (page 160) is enabled, the yellow LED is illuminated.

Echo Tone The frequency response of the delayed (wet) signal can be modified with the Echo Tone controls. These knobs are cut/boost controls; they have no effect when in the 12 o'clock position. The available range is ±10 dB of gain.

Note: The Echo Tone controls do not affect the dry signal.

Treble

Controls the high frequency response in the delayed signals.

Bass

Controls the low frequency response in the delayed signals.

Echo Pan

Pan sets the position of the delayed (wet) signal in the stereo field; it does not affect the unprocessed (dry) signal.

Tip: Click the "Echo" control text to return the knob to center.

Note: When the plug-in is used in a mono-in/mono-out ("MIMO") configuration, the Pan knob does not function and cannot be adjusted.

Input The original hardware unit had two inputs: Instrument and Microphone. The Input switch on the EP-34 toggles between the gain levels of these two inputs.

The "LO" position captures the gain structure of the Instrument input, while the "HI" position captures the gain structure of the Microphone input. This allows for a cleaner (LO) or dirtier (HI) sound depending on the switch position.

Important: Depending on the source material and gain structuring, switching between LO and HI may cause a significant jump in output levels.

Tension

The original hardware provides a tension adjustment screw on the bottom of the Echo Delay slider. Adjusting this tension screw varies the pitch shifting effects (technically, the slew rate) that are obtained when the Echo Delay parameter is manipulated in realtime.

The Tension switch emulates two different tension adjustments of this adjustment screw.

LO

The "LO" position emulates a loose tension adjustment. With this setting, realtime adjustments to the Echo Delay parameter have a faster slew rate, resulting in "snappier" pitch shifting effects.

нι

The "HI" position emulates a tight tension adjustment. With this setting, realtime adjustments to the Echo Delay parameter have a slower slew rate, resulting in "sluggish" pitch shifting effects.

Send The Send switch disables the signal sent into the echo portion of the unit when set to OFF. This control is sometimes affectionately referred to as the "dub switch."

Sync

This switch engages Sync mode for the plug-in. In Sync mode, delay times are synchronized to (and therefore dependent upon) the master tempo of the host application. When Sync is toggled, parameter

units are converted between milliseconds and beats to the closest matching value.

See Chapter 8 in the UAD System Manual for more information about tempo synchronization.

Wet The Wet switch puts the EP-34 into "100% Wet" mode. When Wet is on, it mutes the dry unprocessed signal.

Wet is optimal when the plug-in is used on an effect group/bus that is configured for use with channel sends. When the plug-in is used on a channel insert, this control should be deactivated.

Note: Wet is a global (per plug-in instance) control. Its value is saved within the host project/session file, but not within individual preset files.

Important: Depending on the source material and gain structuring, engaging Wet may cause a significant jump in output levels.

Power

Power determines whether the plug-in is active. This is useful for comparing the processed settings to the original signal, or to by-pass the plug-in to reduce the UAD DSP load (load is not reduced if UAD-2 DSP LoadLock is enabled).

Note: The yellow LED in the Input Meter (page 158) is illuminated when the plug-in is active.

EP-34 Hardware History

Originally designed by Mike Battle in the late 50's as a portable echo device as an answer to the problem of tying up studio tape machines often employed for echo effects. Legendary artists such as Jimmy Page, Miles Davis, Brian May, Andy Summers, Eddie Van Halen among many others have used the hardware to add simple slap echo effects all the way to self-oscillation chaos to their sonic creations. The EP-3 is the favored unit by guitarists, and EP-4 is the last unit that was released and has an improved feature set over its predecessors such as metering and tone controls making it even more useful as a mix tool. Some didn't like the EP-4 because of a noise reduction circuit that was added that was not implemented correctly. Unfortunately in a production mistake, the circuit was placed in across both the direct signal and the tape playback causing the dry source signal sustain to be cut off prematurely. Most modded their units to remove the noise compressor, and Maestro quickly removed the compressor design from the design.

The Echoplex EP-3 hardware unit

*EP-34 Tape Echo is not affiliated with, sponsored nor endorsed by any companies currently using the Echoplex name. The EP-34 Tape Echo name, as well as the EP-3 and EP-4 model names, are used solely to identify the classic effects emulated by Universal Audio's product.

CHAPTER 15

Fairchild Tube Limiter Collection

The Gold Standard in Vintage Tube Limiters

In the annals of compressor history, the products produced by Fairchild are some of the best built and most highly prized on the vintage market. The most famous Fairchild products produced were the 660 and 670 limiters, which are famous for their fantastic sound quality. The stereo Fairchild 670 is probably the "Holy Grail" of limiters in studio gear esoterica, not only because of its price, but also its extreme rareness and the difficulties in maintaining such a unit. With its 14 transformers, 20 vacuum tubes (including 8 of the venerated 6383 gain reduction tubes) and weighing 65 pounds, the Fairchild 670 is truly the heavyweight champion of compression.

Originating from the late 1950's, the design of the 670 uses a single push/pull stage of amplification with an exceptionally high control voltage. Tube limiters are unique in that they use tubes for gain reduction and not just as amplifiers. The audio path is quite simple, and compression happens directly in the audio path, rather than sending out to a separate compression circuit. The unit can be used as a limiter or compressor, depending upon personal taste and program material. It can go from a 2:1 ratio as a compressor to a peak limiter with a 30:1 ratio. The unit can also be adjusted to operate anywhere between these two extremes using the Threshold and DC Threshold controls.

The Fairchild Tube Limiter Collection was created by meticulously modeling (down to the component level) carefully selected hardware. Our "golden reference" channels were modeled from engineer/producer Allen Sides' collection from Ocean Way Recording. The Fairchild plug-ins incorporate all of the features from the original units. Several new UAD-only features round out this offering, giving the UAD Fairchild 670 added flexibility for modern audio production. With a broad range of functionality in the analog world, the Fairchild Tube Limiter Collection's feature set allows for critical master fader uses, and individual sources or subgroups under extreme gain reduction. And you don't have to let it warm up for 30 minutes before use!

Fairchild Tube Limiter Collection Screenshots

Figure 54. The Fairchild 670 plug-in window

Figure 55. The Fairchild 670 Legacy plug-in window

Fairchild Plug-In Family

The complete Fairchild family is comprised of three individual plug-ins, as seen in the screenshots above and described below. Each variation has its own unique sonic characteristics.

Fairchild Tube
Limiter
CollectionThe Fairchild Tube Limiter Collection, introduced in UAD v7.4, includes two
plug-ins: Fairchild 660 and Fairchild 670.

Fairchild 660

The original Fairchild 660 hardware is a single-channel (monophonic) processor. The UAD Fairchild 660 plug-in was faithfully modeled from the original 660 hardware, independently from the Fairchild 670 plug-in modeling.

The Fairchild 660 may be handy with mono sources, or when less control is required via its simpler interface. The Fairchild 660 controls are identical to one channel of the Fairchild 670.

Fairchild 670

The Fairchild 670 is the two-channel (stereo) workhorse revered by engineers and producers worldwide.

Second-Generation Algorithms

The newer state-of-the-art algorithms in the Fairchild Tube Limiter Collection take full advantage of the extra processing power available on UAD-2 devices, along with the design sophistication and expertise gained since the original Fairchild Legacy plug-in was developed.

Sonic Differences

Like the differences between the original Fairchild 660 and 670 hardware units, the UAD models in the Fairchild Tube Limiter Collection offer variations in threshold behaviors, total gain, input attenuation range, distortion amount, distortion structure, program dependence, time constant subtleties and more. These differences provides an expanded palette within the Fairchild sound.

Artist Presets

The Fairchild Tube Limiter Collection includes artist presets from prominent Fairchild users. The artist presets are in the internal factory bank and are accessed via the host application's preset menu.

The artist presets are also copied to disk by the UAD installer so they can be used within Apollo's Console application. These presets can be loaded using the Settings menu in the UAD Toolbar (see "Using UAD Powered Plug-Ins" in Chapter 7 of the UAD System Manual).

The Fairchild Tube Limiter Collection includes additional artist presets that are not available in the internal factory bank. These additional presets can also be accessed using the Settings menu in the UAD Toolbar.

Note: Presets created with the original Fairchild Legacy plug-in are incompatible with the newer Fairchild Tube Limiter Collection plug-ins.

Upsampling

The Fairchild Tube Limiter Collection plug-ins (but not the Fairchild 670 Legacy) use an internal upsampling technique. The upsampling results in a slightly larger latency than most other UAD plug-ins. See "Upsampled Plug-Ins" on page 563 for more information.

Fairchild 670 Legacy	The original version of the Fairchild 670 was released in January of 2004 for the UAD-1 platform. To accommodate the limited DSP resources of the first- generation UAD-1 hardware, the transformer and I/O distortion characteris- tics were not modeled in this version of the plug-in.		
	The Fairchild 670 Legacy has a great sound and is very usable, especially in situations where less distortion is desirable, or when there are not enough DSP resources to use the second-generation models in the newer Fairchild Tube Limiter Collection. It also has slightly less overall latency since it is not an upsampled plug-in.		
	Note: The Fairchild 670 Legacy is included with the purchase of the Fairchild Tube Limiter Collection if it is not already owned.		
Mono/Stereo Operation	Although the Fairchild 660 original hardware is a single-channel processor and the Fairchild 670 original hardware is a dual-channel processor, all plug- ins in the UAD Fairchild family can each be used on either mono or stereo sources.		

Fairchild 670 Operational Overview

Unique Controls Controls in the UAD Fairchild plug-ins are original Fairchild hardware controls with the following exceptions:

- The VU meter and the Meter Switch are re-purposed, enabling the ability to monitor input and output levels (the original hardware does not have this ability). In the hardware, the function of the meter switch is to enable calibrating the bias currents; this function is achieved automatically in the plugin when the Balance control is in the default position.
- The Headroom (HR) control replaces the VU meter's Zero control, which originally corrected for component wear offsets in the VU meter pin.
- The Sidechain Link control is a common modification which had been performed on the unit we modeled.
- Output Level, Controls Link, Sidechain Filter, Mix, and Headroom controls are digital-only additions for the UAD plug-ins.
- The D.C. Threshold controls are original controls, however on the Fairchild 660 they were located on the rear panel.

Note: Not all controls are available in the Fairchild 670 Legacy plug-in.

Lateral/Vertical One of the design goals of the Fairchild 670 hardware was to facilitate its use as a limiter when producing vinyl phonograph masters. The terms lateral (side-to-side) and vertical (up-and-down) refer to the mechanical modulations in a vinyl record groove that are transduced into electrical audio signals by the phonograph stylus and cartridge.

The Fairchild 670 can perform dynamics processing on the lateral ("Lat") and vertical ("Vert") components of stereo signals independently. In other words, the monophonic (middle) and/or stereo (side) components of a stereo source signal can be compressed or limited separately from the other component.

Lat/Vert processing facilitates maximum usable levels and efficient use of available groove space in phonograph mastering, resulting in higher volume recordings with longer playing times. Of course, the feature can also be used for creative effects outside of the phonograph environment.

Note: Lat/Vert processing is an operating mode of Fairchild 670. For additional details on the modes and how to access them, see "Fairchild 670 Modes" on page 168.

Lat/Vert processing is accomplished by first routing the stereo source signal through a sum/difference (mid/side) matrix which separates the stereo source into lateral (middle, or center without stereo) and vertical (side, or stereo without mono) signal components. The lateral/vertical components are then compressed or limited independently. Finally, the mid/side components are recombined into a normal stereo signal via a second sum/difference matrix.

In the Fairchild 670, the left+right (sum) middle signals are routed to the Lat channel, and the left–right (difference) side signals are routed to the Vert channel. The two channels can work independently of each other, or the sidechain control signals can be optionally linked.

Tip: Controls related to Lat/Vert processing contain red Lat/Vert text labels.

Operating Levels The Headroom (HR) control enables adjustment of the internal operating reference level for the Fairchild 670 and Fairchild 660. This feature enables more sonic range and the ability to fine-tune the non-linear I/O distortion and compression response characteristics to be tailored independently of signal input levels.

By increasing the Headroom (by rotating the HR control *counter-clockwise*), signals at the input can be pushed higher before they compress. For complete details about this feature, see "Headroom" on page 173.

Fairchild 670 Modes

- 2 Compressors,4 ModesThere are two independent compressors within the Fairchild 670. Depending on the state of the AGC Switch and the Sidechain Link switch, four operating modes are possible. The modes are detailed in this section.
- **Modes Table** The switch positions required for each operating mode is shown in Table 14 below. See "Lateral/Vertical" on page 167 for an overview of these terms.

Table 14. Fairchild Operating Modes

AGC Switch Setting	Sidechain Link Setting	Operating Mode
Left Right	Unlinked	Dual Mono
Lat Vert	Unlinked	Dual Lateral/Vertical
Left Right	Linked	Stereo Left/Right
Lat Vert	Linked	Stereo Lateral/Vertical

Dual Mono In dual mono mode, the Fairchild 670 operates as two separate monophonic compressors with independent control of the left and right channel signals. There is no interaction between the two compressors.

- **Dual Lat/Vert** In dual lateral/vertical mode the Fairchild 670 operates as two monophonic compressors with independent control of the middle and side components of the two input signals. The input signals are processed by the sum/difference (mid/side) matrix before and after the compressors, but there is no interaction between the two compressors.
- Stereo Left/Right In this mode, the Fairchild 670 operates as a typical stereo dynamics processor. The left input is fed to the one compressor, and the right input is fed to the other. The dynamics control signal sidechain of the two compressors are linked so that they both compress the same amount at any instant, preventing transients which appear on only one channel from shifting the stereo imaging of the output.

Any transient above the threshold (on either channel) will cause both channels to compress, and the amount of compression will be similar to the amount of compression for a transient which appears on both channels at the same time.

Additionally, the attack and release times for the two compressors will be the same, and attack and release behavior will be the average of the settings for the two channels. Mono transients will have an effective attack time of about one half the attack time for transients on only one of the two channels.

Stereo Lat/Vert Stereo lateral/vertical (mid/side) mode, like stereo left/right mode, causes the two compressors to be linked together so that they always compress the same amount. In this mode however, the inputs to the two compressors are fed with the middle and side components of the signal respectively. This generally means that a transient which occurs in both channels will cause a bit more compression than a transient which only appears on left or right. The attack and release behavior is determined by the average of the settings for the two channels.

Fairchild Controls

The control functions are essentially identical across all three UAD plug-ins in the Fairchild family, so they are described only once. Any control differences between the three plug-ins are noted in the control descriptions.

Power Switch This switch determines whether the plug-in is active. When the Power switch is in the Off position, plug-in processing is disabled and UAD DSP usage is reduced (unless UAD-2 DSP LoadLock is enabled).

Power Lamp

The lamp beneath the Power switch is illuminated when the plug-in is active.

Tip: Click the Power Lamp to toggle the enable/disable state of the plug-in.

VU Meters

There are two VU meters, one for each channel. The VU meters can display input levels, output levels, or gain reduction levels, as determined by the Meter Switch.

Meter Switch	This switch determines what is displayed on the VU meters. In- put, output, or gain reduction ("GR") levels can be selected.				
	The default position is GR. If GR is selected, the meter will show gain reduction in dB for the corresponding compressor channel.				
	f the AGC Switch is set to left/right, the GR shown will be for the eft or right channel. If the AGC switch is set to Lat/Vert, the GR hown will be for the middle (upper meter) or side (lower meter) channel. In GR mode, the upper labels show gain reduction in dB.				
	If the meter select switch is set to IN or OUT, then that meter will reflect the rel- ative level of the right or left input or output signal (the I/O meters are not cal- ibrated).				
Channel Input Gain	This is a stepped attenuation control which always applies to left or right input, regardless of the AGC control setting. The steps are approximately 1 dB apart.				
	Fairchild 670				
	The available range is –20 to 0 dB with a default value of –4 dB (unity gain).				
	Fairchild 660				
	The available range is –Infinity (off) to 0 dB with a default value of –14 dB (unity gain).				
	Note: Like the 660 hardware, there is some signal leakage even when Input Gain is set to -Inf.				
	Fairchild 670 Legacy				

The available range is –20 to 0 dB with a default value of –18 dB (unity gain).

Threshold

This continuously variable control determines the amount of compression to be applied to the channel. Rotate clockwise for more compression (increasing the control lowers the threshold).

In the Fairchild 670, the default value is 1.5. In the Fairchild 660, the default value is 5.

Input Gain versus Threshold

The amount of signal compression is determined by both the Input Gain and Threshold controls. If one is increased and the other decreased, the compression characteristics won't change much, but the distortion characteristics will.

The input control is located ahead of the tubes, directly "behind" the input transformer. Therefore as the input control is increased, the input tube (the gain-varying stage) is hit with more signal which can increase distortion (which may or may not be desirable).

Tip: For less distortion with the same amount of compression, lower the input gain and increase the threshold control.

Time Constant This 6-position switch provides fixed and variable time constants (attack and release times) to accommodate various types of program material. Positions 1-4 provide successively slower behavior, and 5 and 6 provide program dependent response.

The values published by Fairchild for each position are in

Table 15 below. The actual measured times are a bit different, but the overall trend is the same. The default value is Position 5.

Tip: When Sidechain Link is enabled and Controls Link is disabled, the Time Constant settings of the two channels are interactive, which enables the ability to have many other attack/release variations than those listed in the table.

Time Constant	Attack Time	Release Time
Position 1	200 microseconds	300 milliseconds
Position 2	200 microseconds	800 milliseconds
Position 3	400 microseconds	2 seconds
Position 4	800 microseconds	5 seconds
Position 5	200 microseconds	Program dependent:
		2 seconds for transients
		10 seconds for multiple peaks
Position 6	400 microseconds	Program dependent:
		300 milliseconds for transients
		10 seconds for multiple peaks
		25 seconds for consistently high program level

Table	15.	Fairchild	Time	Constants
rabic	10.	1 an orma	THILD	Constants

AGC Switch

This switch determines whether the two compression channels will receive left/right or lateral/vertical (mid/side) signals as the inputs.

In conjunction with the Sidechain Link switch, this control determines the operating mode of the Fairchild 670. See "Fairchild 670 Modes" on page 168 and Table 14 on page 168

for detailed mode descriptions.

Note: This control is unavailable on the Fairchild 660.

Left/Right

If Left/Right is selected and Sidechain Link is off, the compressor is in dual mono mode. If Sidechain Link is on, the mode is stereo left/right.

Lat/Vert

If Lat/Vert (mid/side) is selected and Sidechain Link is off, the compressor is in dual lateral/vertical mode. If Sidechain Link is on, the mode is stereo lateral/vertical.

Sidechain Link

When this control is set to Link, it causes the two channels of the compressor to compress in equal amounts. This does not mean that the compressor will be equally sensitive to either channel however; that depends on the settings of the other controls.

Note: This control is unavailable on the Fairchild 660.

Linking the sidechains simply means that the instantaneous amount of compression for the two channels will always be the same, thereby preventing leftright image shifting at the output. Threshold and input gains can be set independently to cause the compressor to be more sensitive to instruments which are panned to one side or the other. Output controls can be set separately in order to correct an overall image shift at the output.

Tip: In conjunction with the AGC Switch switch, the Sidechain Link switch determines the operating mode of the Fairchild 670.

Controls Link

This switch allows the two sets of controls for the interface to be stereo linked. The control is unavailable on the Fairchild 660.

Important: When unlink is switched to link, the left channel values are copied to the right channel, and any control offsets between channels are lost.

Overview

The Fairchild hardware units can accept an analog signal level of approximately +27 dBm before undesirable signal clipping occurs. As the signal increases up to this point however, desirable audio-path nonlinearities and "good" harmonic distortion characteristics occur. This musically pleasing "warmth" at higher levels is what gives the unit much of its revered sonic character. Because analog mixing consoles can typically output high signal levels, audio engineers often take advantage of the ability to "push" the hardware unit into the colorful arena.

This complete pallet of sonic nuance, including the dynamic input response, is captured in the Fairchild Tube Limiter Collection models (but not the Fairchild 670 Legacy). The 660 and 670 plug-ins are calibrated internally so that when the Headroom control is at its nominal value of 16 dB, 0 dBFS at their input is equivalent to an input level of approximately +20 dBu on the hardware, where the coloring is more prominent. The result is that a typical signal within a DAW will drive the UAD Fairchild 660/670 into these "virtual" higher levels, resulting in fairly high amounts gain reduction.

Headroom Control

The Headroom control (labeled "HR") is provided to accommodate applications where high amounts of gain reduction are not desired. Headroom simply changes the internal operating level so that the plug-in is not "pushed" into gain reduction as much.

Note: There is only one headroom parameter. Although the HR control appears twice in the Fairchild 670 window, they are permanently linked.

Headroom can be set (in dB) to 4, 8, 12, 16, 20, 24, or 28. The default value is 16 dB (when the set screw "dot" is in the straight up 12 o'clock position). Note that Headroom is *increased* as the dB value *decreases*.

Tip: Click the "HR" text label to return the control to the default value.

At higher dB values (clockwise rotation), signals will push the plug-in into gain reduction (and more non-linearity and "good" harmonic distortion color) more easily. Set the control to a lower value (counter-clockwise rotation) when less gain reduction and less color is desired.

Note: To avoid the temporary gain increases that can result when adjusting Headroom, automating this control is not recommended.

Keep in mind there are no hard and fast headroom rules. Feel free to experiment with the various positions of the HR control regardless of the audio source. If it sounds good, use it!

Note: The HR control does not exist on the Fairchild 670 Legacy. On the hardware unit, the Zero screw (as displayed in the Fairchild 670 Legacy) adjusted the meter pointer to compensate voltage fluctuation and component wear.

Balance Balance controls the bias current balance. It always controls one channel of the compressor, regardless of what the nearby Meter Switch is set to. The point of perfectly calibrated bias currents is achieved when the screw slot is at the 12 o'clock position (the default value). At this setting, the amount of additive signal deflection

BAL

fault value). At this setting, the amount of additive signal deflection ("thud") which happens due to an attack is minimized. Setting this control counterclockwise from this position results in a thud of one polarity on transients, and going clockwise produces a thud of opposite polarity.

Tip: Click the "BAL" text label to return the control to the default position.

Note: To avoid the DC settling artifacts that can result when adjusting Balance, automating this control is not recommended.

The Sidechain Filters (one each for the Left/Lat and Right/Vert channels) control the cutoff frequency of a low-cut filter on the compressor's control signal sidechain. They have a slope of 12 dB per octave. The available range is 20 Hz to 500 Hz, and Off. The default value is Off.

Tip: Click the OFF label to disable the sidechain filter.

Removing low-frequency content from the sidechain can reduce excessive gain reduction and/or "pumping" on bass-heavy audio signals without reducing bass content of the audio signal itself.

Auditioning the Sidechain Filter

To quickly switch back and forth between OFF and the last set value, click the OFF label. This feature is handy for comparing the filtered and unfiltered sidechains.

Note: The Sidechain Filter affects the control signal of the compressor only. It does not filter the audio signal.

Sidechain Filter

DC Threshold DC Threshold controls the ratio of compression as well as the knee width. As the knob is turned clockwise, the ratio gets lower and the knee gets broader. The threshold also gets lower as the knob is turned clockwise.

It's more technically accurate to say that this control simply changes the knee width, since no mat-

ter where it's set, the ratio always approaches true limiting eventually. However, the knee becomes so broad that it becomes more practical to speak of the ratio changing, because for reasonable amounts of compression (less than 25 dB), this is the case.

Note: This control is labeled DC Bias on the Fairchild 670 Legacy.

CAL

To calibrate the plug-in to factory specifications (the default value), align the white "CAL" mark with the black "dot" on the adjustment screw.

Tip: Click the "CAL" text label to return the control to the factory calibrated position.

OWR

To calibrate the plug-in to the setting used by Ocean Way Recording (the source unit for the plug-in modeling), align the white "OWR" mark with the black "dot" on the adjustment screw.

Tip: Click the "OWR" text label to return the control to the Ocean Way Recording position.

Output Gain

These controls provide clean, uncolored gain to the output signals. The available range is ±20 dB. The default value is 0 dB.

Tip: Click the "OUTPUT" text label to return the control to the default position.

Note: In the Fairchild 670 Legacy this is a stepped control, with each step being separated by 0.5 dB, and an available range of -18 dB to +6 dB.

The output balance between the signal processed by the plugin and the original dry source signal can be adjusted with the Mix control. Mix facilitates parallel compression techniques without having to create additional routings in the DAW.

M1X* 50 0 1/0%

When set to 0%, only the unprocessed (dry) source signal is output. When set to 100% (the default value), only the pro-

cessed (wet) signal is output. When set to 50%, an equal blend of both the dry and wet signals is output. The balance is continuously variable throughout the control range.

Tip: Click the "MIX" text label to set the control to the 50% position. Click the "0" text label to set the control to the minimum position. Click the "100%" text label to set the control to the maximum position.

Mix

Historical Background

The origins of the Fairchild 660/670 design come from Estonian-born immigrant Rein Narma. Les Paul hired Narma to modify his first 8-track Ampex machine. Later, Narma built consoles for Olmsted Recording, Rudy Van Gelder, and Les Paul, who then asked him to build an all-new, sonically reliable audio limiter. In the post-war years, this refugee from Soviet Russia worked for the U.S. Army as a broadcast/recording tech during the Nuremberg trials, then later immigrated to the New York and took a job at Gotham Recording. Narma and others founded Gotham Audio Developments to build recording gear.

The compressor's Fairchild connection begins with Sherman Fairchild, the son of Congressman George Winthrop Fairchild, one of the founders of IBM. Sherman Fairchild built and designed the first aerial photography equipment during World War I. After that war ended, he started the Fairchild Aerial Camera Corporation in 1920. Sherman Fairchild eventually went on to design a multitude of products, from aircraft to semiconductors, and opened several more companies, including Fairchild Recording Equipment Corporation. After Narma began the limiter project for Les Paul, Sherman Fairchild heard about it, licensed the design, and hired Narma as the company's chief engineer. After his time at Fairchild, Narma moved to Northern California and was a vice-president at Ampex. The Fairchild was advertised as "The World Accepted Standard for Level Control" back in the 1950s when it was originally sold. It is still revered for its extremely smooth, artifact-free sound.

The Fairchild 660 and 670 Original Hardware

CHAPTER 16 Harrison 32C EQ

Overview

The Harrison 32C is the EQ channel module from the prestigious Harrison 4032 console. Countless hit records have been made with Harrison consoles, with artists from Abba to Sade. Most notably, the 4032 is famous as the mixer from which many Michael Jackson records including Thriller—the best-selling album of all time—were made. An original 4032 still resides in Florida with Thriller engineer and Bill Putnam protégé Bruce Swedien, where he continues his love affair with the desk he calls "marvelous sounding." Universal Audio's plug-in version of the all-important 32C EQ module is measured from Mr. Swedien's personal console. This colorful 4-band EQ with high and low cut filters will impart the same "warm and rich sound" from his Harrison, and will impart the same "impact, sonic clarity and creativity" as he experienced making some of the best-loved records of our time.

The Harrison 32C contains four overlapping parametric peaking bands. Each band has fully sweepable Frequency and Gain controls. Instead of traditional Q controls, the 32C has special circuitry that, according to the original hardware documentation, "automatically adjusts the effective bandwidth under all conditions." This dynamic property, and the interplay between the overlapping bands, contribute to the device's musicality and unique sonic signature.

The low EQ band can be switched from peak to shelf mode, and high/low pass filters are available. Additional "digital only" features not included on the original hardware include gain, phase invert, and a global power switch. An SE version is also provided for higher instance counts.

Harrison 32C EQ Screenshot

Figure 56. The Harrison 32C EQ plug-in window

Harrison 32C EQ and Harrison 32C SE Controls

Note: Knob settings, when compared to the graphical user interface silkscreen numbers, may not match the actual parameter values (e.g., if a knob is pointing to 8 kHz, the actual frequency may not be 8 kHz). This behavior is identical to the original hardware, which we modeled exactly. When the plug-in is viewed in parameter list mode (Controls View), the actual parameter values are displayed.

Power The Power switch determines whether the plug-in is active. Click the button to toggle the state. When the Power switch is in the Off (lighter) position, plug-in processing is disabled and UAD DSP usage is reduced (unless UAD-2 DSP LoadLock is enabled).

Power LED The Power LED is illuminated when the plug-in is active.

Phase The Phase (Ø) button inverts the polarity of the signal. The signal is inverted when the button is engaged (darker). Leave the button inactive (lighter) for normal phase.

In addition to the four-band EQ, the Harrison 32C offers two cut filters, one each for low and high frequencies. The slope of the cut filters is 12 dB per octave.

Cut Enable

The high and low pass filters are engaged with the Cut Enable switch. The

Cut Filters are active when the "In" switch is engaged (darker). When the Cut Filters are engaged, circuit coloration is modeled even when set to "zero cut" frequency values (25 Hz and 20 kHz respectively).

The Cut Enable "In" switch is to the left of the EQ "In" switch on the graphical interface.

High Pass (low cut)

This control determines the cutoff frequency for the high pass filter. The available range is 25 Hz to 3.15 kHz.

Cut Filters
Low Pass (high cut)

This control determines the cutoff frequency for the low pass filter. The available range is 1.6 kHz to 20 kHz.

Four EQ Bands	Each of the four EQ bands have similar controls. The band center frequency is controlled the top row of knobs, and the band gain is controlled by the bottom row.
Low Peak	The low EQ band can be operated in either peak or shelf mode. When the Low Peak switch is in the "out" position, the low EQ band operates in shelf mode. When the Low Peak switch is engaged (darker), the low EQ band operates in peak mode (the other bands always operate in peak mode).
Low Frequency	This control determines the low band center frequency (or the edge frequency when in shelf mode) to be boosted or attenuated by the band Gain setting. The available range is 40 Hz to 600 Hz.
Low Gain	This control determines the amount by which the frequency setting for the low band is boosted or attenuated. The available range is ±10 dB.
Low Mid Frequency	This control determines the low midrange band center frequency to be boosted or attenuated by the band Gain setting. The available range is 200 Hz to 3.1kHz.
Low Mid Gain	This control determines the amount by which the frequency setting for the low midrange band is boosted or attenuated. The available range is ±10 dB.
High Mid Frequency	This control determines the low midrange band center frequency to be boosted or attenuated by the band Gain setting. The available range is 400 Hz to 6 kHz.
High Mid Gain	This control determines the amount by which the frequency setting for the high midrange band is boosted or attenuated. The available range is ±10 dB.
Hi Frequency	This control determines the high band center frequency to be boosted or at- tenuated by the band Gain setting. The available range is 900 Hz to 13 kHz.

Hi Gain This control determines the amount by which the frequency setting for the high band is boosted or attenuated. The available range is ±10 dB.

Gain

The Gain knob controls the signal level that is output from the plug-in. The default value is 0 dB. The available range is ± 10 dB.

Harrison 32C SE

Figure 57. The Harrison 32C SE plug-in window

Overview The UAD Harrison 32C SE is derived from the UAD Harrison 32C. Its algorithm has been revised in order to provide sonic characteristics very similar to the Harrison 32C but with significantly less DSP usage. It is provided to allow Harrison-like sound when DSP resources are limited. Nobody with "golden ears" will say it sounds exactly like the full version, but it still sounds great and is very usable in most situations.

The Harrison 32C SE interface can be differentiated from the Harrison 32C by knob color and the module name. The Harrison 32C SE blue knobs instead of the Harrison 32C's ivory knobs, and the module name on the upper right of the interface panel includes "SE."

Harrison 32C SE
ControlsThe Harrison 32C SE controls are exactly the same as the Harrison 32C.
Please refer to the Harrison 32C section for Harrison 32C SE control descrip-
tions (see "Harrison 32C EQ and Harrison 32C SE Controls" on page 180).

Harrison 32C Latency

The Harrison 32C (but not the Harrison 32C SE) uses an internal upsampling technique to facilitate its amazing sonic accuracy. This upsampling results in a slightly larger latency than other UAD plug-ins. See "Upsampled Plug-Ins" on page 563 for more information.

The Harrison 32C SE does not require additional latency compensation because it is not upsampled.

Note: Compensating for Harrison 32C is not required if the host application supports full plug-in delay compensation throughout the signal path, or when it is used only on the outputs.

The Harrison 4032 Console, featuring the Harrison 32C EQ

Special thanks to Bruce Swedien for his gracious cooperation with the UAD Harrison 32C project.

CHAPTER 17

Helios Type 69 Equalizer

Overview

Helios consoles were used to record and mix some of the finest rock, pop and reggae classics ever produced. The Beatles, Led Zeppelin, The Rolling Stones, The Who, Roxy Music, Queen, Jimi Hendrix and Bob Marley are just a few that recorded with these amazing wrap-around consoles. Moreover, many great musicians of the era purchased Helios consoles for their personal use. Of all the Helios consoles produced between 1969 and 1979, the original "Type 69" is considered the most musical. Universal Audio modeled the EQ section of the very first Type 69. This console was originally found at Island's Basing Street Studio in London; it now resides with Jason Carmer in Berkeley, California, where it continues to record multi-platinum albums.

Helios Type 69 Screenshot

Figure 58. The Helios Type 69 plug-in window

Helios Type 69 Controls

Overview

The simple yet powerful Helios Type 69 Passive EQ adds a unique sonic texture to the music that passes through it. It can be pushed to its most extreme boost settings while retaining openness and clarity. The Type 69 Passive EQ replicates all the controls of the original hardware. The Treble band is a fixed 10 kHz shelf EQ, while the Bass band functions as a stepped 50 Hz shelf filter (-3,-6,-9,-12,-15 dB) or frequency selectable Peak EQ (60, 100, 200, 300 Hz). The Mid band operates as a frequency selectable Peak or Trough (Notch) EQ with eight frequencies (.7, 1, 1.4, 2, 2.8, 3.5, 4.5, 6 kHz). Other features include Level Adjust, EQ Cut (bypassing the EQ circuit while retaining the native sound of the unit), and Phase Reverse.

Band Layout

Figure 59. Helios 69 band control layout

The Helios Type 69 design works in such a way that (depending on the settings) entire EQ circuits are switched in and out. In the hardware that often meant audible popping. For the plug-in we use smoothing to reduce these audio spikes, but they may be more audible than with other UAD plugs-ins. This is most audible when engaging the Bass or 10 kHz band from OFF to any other setting.

Each feature of the UAD Helios 69 interface is detailed below.

The Bass knob has a dual purpose. It specifies the amount of attenuation when the low band is in shelving mode, and specifies the frequency of the low frequency peak filter when the Bass Gain knob is not zero.

When Bass is set to one of the frequency values (60 Hz, 100 Hz, 200 Hz, or 300 Hz) the low band is in peak

mode. In this mode, the amount of gain ("bass boost") applied to the specified frequency is determined by the Bass Gain knob.

When this knob is set to one of the decibel values (-3, -6, -9, -12, -15 dB) the low band is in "bass cut" shelving mode with a set frequency of 50 Hz.

Note: Like the original hardware, simply putting this control on any frequency will yield approximately 3.5 dB in gain increase even if the Bass Gain control is set to 0.

Bass Gain

The Bass Gain knob determines the amount of low band gain to be applied when the Bass knob is in one of the frequency positions. Up to +15 dB of boost is available.

Note: Bass Gain has no effect when the Bass knob is in shelving mode (when Bass set to one of the dB positions).

Mid Freq

This control determines the frequency of the midrange band. The following frequencies can be specified: 700 Hz, 1 kHz, 1.4 kHz, 2 kHz, 2.8 kHz, 3.5 kHz, 4.5 kHz, and 6 kHz.

Note: The gain for the mid band is determined by the Mid Gain control. MidFreq has no effect if the Mid Gain control is set to zero.

In the graphic interface of this control, what may appear to be a dash ("-") actually represents a decimal point. This anomaly mimics the original hardware.

Mid Gain

This control determines the amount of gain or attenuation to be applied to the mid band. Up to 15 dB of boost or cut is available.

The Q (bandwidth) on the midrange band is fairly wide and gentle at low settings, but gets progressively narrower as the gain value is increased.

Note: Whether gain or attenuation is applied is determined by the Mid Type control.

Mid Type Mid Type specifies whether the midrange band is in Peak or Trough mode. When switched to Peak, the Mid Gain control will boost the midrange. When switched to Trough, Mid Gain will cut the midrange.

> **Note:** When using Trough, a 1 dB loss occurs on the overall output of the plugin. This is normal; the behavior is the same in the original hardware.

High Shelf Gain

The High Shelf Gain knob offers fixed frequency shelving equalization at 10 kHz. This stepped control can cut the treble by -3 dB or -6 dB, or boost it in 2 dB increments up to +16 dB.

EqCut

This switch is an EQ bypass control. It allows you to compare the processed and unprocessed signal. The EQ is active when in the "in" (up) position.

The EQ is bypassed when in the "out" (down) position. EqCut does not reduce UAD DSP load.

In the original Helios hardware, the audio is still slightly colored even when the EQ switch is in the Cut position. This is due to the fact that the signal is still passing through its circuitry. Because the plug-in emulates the hardware in every regard, the signal will be slightly processed when this switch is in the Cut position. If a true bypass is desired, use the Line switch instead.

Phase

The Phase (\emptyset) switch inverts the polarity of the signal. When the switch is in the "Inverted" (up) position, the phase is reversed. Leave the switch in the "Normal" (down) position for normal phase.

Level Adjust

This control adjusts the signal output level of Helios Type 69. This may be necessary if the signal is dramatically boosted or reduced by the EQ settings. The available range is -20 dB to +10 dB.

Line

The Line switch determines whether the plug-in is active. This is useful for comparing the processed settings to the original signal, or to bypass the plug-in to reduce the UAD DSP load (load is not reduced if UAD-2 DSP LoadLock is enabled).

Click the switch to toggle the state; the switch is illuminated in green when the plug-in is active.

Helios 69 Latency

The Helios 69 uses an internal upsampling technique to facilitate its amazing sonic quality. This upsampling results in a slightly larger latency than other UAD plug-ins. See See "Upsampled Plug-Ins" on page 563. for more information.

Note: Compensating for Helios 69 is not required if the host application supports full plug-in delay compensation throughout the signal path, or when it is used only on the outputs.

Basing Street—Home of the original Type 69 Helios desk

The same desk, now in Berkeley's Morningwood, nearly 40 years later

CHAPTER 18 Ibanez Tube Screamer TS808

The Most Iconic Overdrive Pedal Ever Created

Released in 1979, the Ibanez Tube Screamer TS808 overdrive pedal quickly became legend for its dynamic, touch-sensitive distortion and throaty midrange. A mainstay on the pedalboards of Stevie Ray Vaughan, Eric Johnson, Brad Paisley, Trey Anastasio, and Joe Bonamassa, the TS808 holds a hallowed place in guitar lore.

The Ibanez Tube Screamer has inspired hundreds of knock-offs and vintage units command insane prices. Now, for the first time, you can track through the only Ibanez-licensed TS808 emulation with the Ibanez Tube Screamer TS808 for UAD-2 and Apollo interfaces.

Now You Can:

- Track through a stunning emulation of the legendary Ibanez Tube Screamer TS808 with Apollo Twin, DUO, or QUAD
- Add colorful distortion textures to guitars, synths, drums, and vocals at mixdown with any UAD-2 hardware
- Get the same circuit interaction, gain range, and clip points of a vintage TS808 Tube Screamer thanks to Unison technology for Apollo Twin, DUO, and QUAD
- Use the TS808 plug-in in front of an already-overdriven amp model, adding body and sustain to your sound

Dynamic Distortions The Ibanez Tube Screamer TS808 for UAD-2 and Apollo nails every detail of this vintage grind machine, allowing guitarists of all styles a vast array of sounds at tracking or mixdown. Key to this is capturing the original's unique circuit, which actually mixes the clean input signal with the output signal of the TS808's clipping circuit — preserving your playing dynamics and actually improving clarity and responsiveness.

From Subtle Rhythms to Searing Solos	No matter what type of guitar you're using, the TS808 plug-in can transform your tones with its signature character. Use it to add a touch of dirt to ringing chords, enhancing your guitar's string-to-string separation, or crank the Level and Drive controls to unleash the TS808's legendary creamy, singing midrange. You can also call on the TS808 plug-in to deliver chunky rhythm tones à la Keith Richards.
Unison Technology for Authentic Tube Screamer Tones	The interaction of your instrument and the first pedal in your signal chain is an essential ingredient to capturing a stompbox's unique character and tone. Thanks to Universal Audio's Unison technology, your guitar gets the same circuit interaction, gain range, and clip points of a vintage Tube Screamer when you plug in to an Apollo Twin, DUO, or QUAD. This gives you the true tone, feel, and response of the original hardware.
An Essential Tone Stage for Tracking and Mixing	Creative producers and engineers have employed the Ibanez TS808 in myr- iad ways. Producer/engineer Andy Sneap (Megadeth, Kreator, Exodus) runs a TS808 in front of an amp to lean-out the bass response and add teeth, while Joe Barresi (The Melvins, Tool, Weezer, and Bad Religion) uses a vintage TS808 at mixdown to add texture and distortion to already-tracked guitars, synths, drums, and vocals. The Ibanez Tube Screamer TS808 for UAD-2 and Apollo allows you to do the same thing, effortlessly in your DAW.

Figure 60. The Ibanez Tube Screamer TS808 plug-in window

Using Ibanez Tube Screamer

Standard DAW Inserts In much the same way as some premier recording and mix engineers use stomp boxes in a mix, Ibanez Tube Screamer can be used for creative purposes on any source signal by placing it in any plug-in insert within a DAW. For typical guitar tones, follow the pedal with a guitar amp emulation (as one would with a hardware guitar pedal and amp).

> Because the plug-in accurately models the original hardware's high-impedance operating levels, precautions may need to be taken to avoid undesirable input clipping.

> **Note:** Since Hi-Z devices typically operate at much lower signal levels than line-level devices, signal levels being routed into the pedal may need to be reduced to avoid undesirable input distortion.

Unison™ Technology with Apollo The Ibanez Tube Screamer features Unison technology for integration with the high-impedance input hardware in Universal Audio's Apollo audio interfaces. With Unison, Apollo's Hi-Z inputs inherit all of the unique circuit interaction, gain range, and clip points of the original guitar pedal.

Hi-Z Signal Routing

For the most authentic stompbox tones, plug any high-impedance instrument (guitar, bass, etc.) into Apollo's Hi-Z instrument input and place the pedal plug-in into the unique Unison INPUT insert on the same channel within Apollo's Console application. If desired, follow the Unison pedal plug-in with another pedal or guitar amp emulation in Console's standard insert slots.

This Hi-Z workflow enables near-zero latency monitoring or recording with the same input characteristics and dynamic response as the original pedal.

Note: This plug-in can be Unison-enabled with Apollo's Mic or Line inputs. However, because the original hardware has a high-impedance instrument input only, Apollo's Hi-Z input and Unison insert will provide the most accurate sound and experience of the hardware pedal that is modeled.

Important: Unison is active only when the pedal plug-in is placed in the unique INPUT insert available on Hi-Z inputs within Apollo's Console application. For complete Unison details, see the Apollo Software Manual.

Tactile Control

Apollo's front panel preamp knob can independently adjust the Overdrive, Level, and Output controls available within the Unison pedal plug-in via Gain Stage Mode. The control being adjusted can be remotely switched via Apollo, so the control levels and their associated colorations can be tuned from the hardware knob for precise physical tactile control, all without using the Unison plug-in's software interface.

Ibanez Tube Screamer Controls

Overdrive	Overdrive varies the amount of signal distortion. Rotate the control clockwise to increase overdrive and sustain.
Tone	Tone adjusts the high-frequency content of the signal. Rotate the control clockwise to decrease the filter amount, which increases treble content.
Level	Level adjusts the pedal's modeled output level. Rotate the control clockwise to increase the volume.
Bypass	The stomp switch toggles the overdrive effect. When the effect is active, the red LED (above the Tone knob) glows. Like the original hardware, this is a not a "true bypass" switch. When the effect is inactive, the signal is still colored by the cir- cuitry.
	Tip: For true bypass, click the UA diamond logo.
Output	Output controls the clean (unmodeled) gain at the output of the plug-in. The available range is -24 dB to +12 dB. Tip: Click the "0" label to return the control to zero dB.

Power The UA diamond logo switch toggles between plug-in enable and disable (true bypass). Click the switch to toggle the Power state.

When Power is off, the UA diamond logo is dim and the external power supply cable is unplugged.

Tip: Power can also be toggled by clicking the image of the external power supply cable.

Figure 61. The unplugged power cable in true bypass mode

All visual and aural references to the Ibanez Tube Screamer TS808 and all use of Ibanez's trademarks are being made with written permission from Ibanez.

CHAPTER 19-

LA-3A Compressor

Overview

The original Teletronix LA-3A Audio Leveler made its debut at the 1969 New York AES show. Marking a departure from the tube design of the LA-2A Leveling Amplifier, the solid-state LA-3A offered a new sound in optical gain reduction, with faster attack and release characteristics that were noticeably different from its predecessor. Immediately embraced as a studio workhorse, the LA-3A is still widely used today. Engineers and producers the world over favor the LA-3A for its unique compression characteristics and sonic signature. Modeled from a unit in UA's vintage collection, our digital emulation of the LA-3A faithfully captures the hardware's sound, working magic on vocals, guitars and drums.

LA-3A Screenshot

Figure 62. The LA-3A plug-in window

LA-3A Controls

Background	For detailed information about compressors, see "The LA-2 captures one of the earliest Teletronix examples. This exceedingly rare unit preceded the LA- 2A by a few years and incredibly, still has the original T4A fully intact. The LA- 2 provides the slowest response and a unique "mellowed" sound due to 50 years of luminescent panel aging inside the T4 module. Use the LA-2 with le- gato tempos and your most vowel-like sources for a transparency and sublime mood unlike any other compressor." on page 518.
Comp/Lim	This switch changes the characteristics of the compressor I/O curve. When set to Compress, the curve is more gentle, and presents a low compression ra- tio. When set to Limit, a higher compression ratio is used.
Gain	The Gain knob adjusts the output level (by up to 50 dB). Make sure to adjust the Gain control <i>after</i> the desired amount of compression is achieved with the Peak Reduction control. The Gain control does not affect the amount of com- pression.
Peak Reduction	This control adjusts the amount of gain reduction, as well as the relative threshold. A Peak Reduction value of 0 yields no compression. Rotate this con- trol clockwise until the desired amount of compression is achieved (to monitor the Peak Reduction, set the VU Meter to Gain Reduction). The Peak Reduction should be adjusted independently of the Gain control.
Meter	This switch sets the mode of the VU Meter and also disables the plug-in. When set to Gain Reduction, the VU Meter indicates the Gain Reduction level in dB. When set to output, the VU Meter represents the output level (the output meter is not calibrated).
	When in the Off position, the plug-in is disabled and UAD DSP usage is re- duced.
	Note: (UAD-2 only) UAD-2 DSP usage is reduced only when DSP LoadLock is disabled. If DSP LoadLock is enabled (the default setting), setting the switch to Off will not reduce DSP usage.
Stereo Operation	Phase-coherent stereo imaging is maintained when the LA-3A plug-in is used on a stereo signal.

CHAPTER 20 Lexicon 224

Classic Digital Reverb

From the moment it was unleashed on the audio industry in 1978, the original Lexicon 224 Digital Reverb — with its tactile, slider-based controller and famously lush reverb tail — almost single-handedly defined the sound of an entire era. It served as a major player in the sound of highly influential classics such as Talking Heads' Remain In Light, Grandmaster Flash & The Furious Five's The Message, Vangelis' incredible Blade Runner soundtrack, U2's Unforgettable Fire, and Peter Gabriel's So. With such a refined legacy, it's no surprise that the Lexicon 224 remains one of the most popular digital reverb units of all time.

The result of using the very same algorithms and control processor code from the original hardware, the UAD-2 Lexicon 224 precisely captures all eight reverb programs and the chorus program — based on the Lexicon 224's final and hard-to-find firmware version 4.4. In UA's exhaustive modeling tradition, the Lexicon 224 plug-in also incorporates the original unit's input transformers and early AD/DA 12-bit gain stepping converters — nailing the entire analog and digital circuit paths right down to the last detail.

Additionally, the Lexicon 224 emulation for UAD-2 features direct input and presets from famous Lexicon 224 users, including Chuck Zwicky (Prince, Jeff Beck), Eli Janney (Jet, Ryan Adams), David Isaac (Eric Clapton, Luther Vandross), E.T. Thorngren (Talking Heads, Bob Marley), and Kevin Killen (U2, Peter Gabriel).

History Developed by renowned physicist/engineer Dr. David Griesinger, the Lexicon 224 is the most ubiquitous and best-selling studio digital reverb ever made. The original 224 was a landmark achievement in digital reverb and served as the very product to put Lexicon on the studio map — and a remote control on every console. The 224's Concert Hall A program is considered to be one of the finest reverbs ever made, and its plate programs practically defined the 80's drum sound. **Parameters** Every tunable parameter from the original is present in the Lexicon 224 plug-in, and exposed as dedicated controls — inviting easy experimentation and sonic exploration. All seven algorithms/nine programs are available under the Program selection. Lexicon's distinctive Bass/Mid "split decay" adjustments and Crossover control set the highly tunable reverb image, along with the Treble Decay for rolling off high frequencies. Depth sets the apparent distance between source and reverb, while Predelay produces a short delay between the sound source and the onset of reverberation. Diffusion affects how quickly the echo density in the reverb builds up over time.

For total authenticity, the UAD-2 only System Noise control enables or disables the inherent dynamic system noise of the original Lexicon 224 hardware. Specifically, disabling System Noise enables a more modern (i.e., cleaner) sound, removing the modeled gain stepping, parameter zippering, and quiescent noise. The unique Lexicon 224 Mode Enhancement and Decay Optimization controls improve reverb clarity. For insert use, the UAD-2 only Dry/Wet and Solo parameters control the effect mix within the plug-in.

Clicking the "OPEN" text to the right of the display panel exposes several hidden controls, including Input/Output gain and Pitch Shift, and even a selectable "Bug Fix" mode which enables/disables historical bugs fixes from the Hall B and Chorus programs.

Taken together, the Lexicon 224 emulation for UAD-2 is the world's most exhaustive and authentic model of a true studio classic.

The original Lexicon 224 Digital Reverberator hardware

All visual and aural references to Lexicon products and all use of Lexicon trademarks are being made with written permission from Harman International Industries, Inc.

Figure 63. The Lexicon 224 plug-in window

Operational Overview

Graphical User Interface The original Lexicon 224 consists of two hardware elements. The "mainframe" rack-mountable 4U chassis contains the power supply, circuitry, and audio input/output connectors. The remote control unit has a display, buttons, and sliders which control the 224 parameters and functionality. Some of these buttons and sliders have dual and even triple functionality, which makes using certain "buried" functions a tricky procedure.

> The UAD Lexicon 224 interface resembles the appearance and functionality of the original hardware remote control. Operation has been simplified however by reassigning the buried "shift" functions to the buttons that are no longer necessary in a plug-in (such as managing saved programs). Additional parameters are exposed by opening a panel cover.

Lexicon 224 ProgramsThe original Lexicon 224 hardware has "programs" that are defined by the firmware ROM ("Read-Only Memory" chip) installed in the unit. A Lexicon 224 "program" is comprised of a unique DSP algorithm and an initial set of factory parameter values voiced by Lexicon. In modern terminology, these initial values would be called a "preset."

In Lexicon 224 hardware-speak, a program is "called" (loaded) which selects the DSP algorithm and sets the default "recommended" factory parameter values. These settings can then be modified with the various controls and saved in a user "register" for later recall. The plug-in behaves the same way, except user "registers" are not implemented. Instead, user settings are stored within the session file or they can be saved as a preset for later recall (like all other UAD plug-ins).

Lexicon 224 version 4.4 firmware contains nine programs (the maximum available for the unit), consisting of eight reverb programs and one chorus program. Descriptions of the various programs can be found on page 215.

Lexicon 224 Algorithms The active algorithm determines the inherent sonic character of the current program. Algorithms are changed by selecting a different program; the algorithm cannot be changed within the same program.

Lexicon 224 v4.4 contains seven unique algorithms. All seven algorithms and the nine factory programs have been authentically modeled in the UAD Lexicon 224 plug-in. There are more programs than algorithms because some programs use the same algorithm. See "Program Descriptions" on page 215 for details.

Lexicon 224 Buttons	Like the original hardware, UAD Lexicon 224 buttons are momentary-style and don't latch in a down position. When a function is unavailable within a particular program, the button's LED will not illuminate when clicked (the LEDs also don't illuminate for the increment/decrement buttons).
	The first click of an increment/decrement button displays the current value of the parameter; the value is actually changed only with subsequent clicks. This feature enables viewing the current setting without changing it.
	Tip: For the inc/dec buttons (e.g., Reverb Diffusion), the value can be continuously changed by holding the button down.
Lexicon 224 Sliders	The six sliders control the main reverb parameters within a program. These are the most obvious controls to reach for when fine-tuning a reverb program to best suit the material at hand.
	In P9 Chorus A, the first four sliders don't control the labeled parameters. See "P9 Chorus A" on page 216 for descriptions of the sliders in this program.
	Tip: Clicking a slider "cap" will show its value in the Numerical Display. Clicking the text label of any slider will return that slider to the default value for the active program.
Inputs & Outputs	The Lexicon 224 hardware has two inputs (see Mono/Stereo below), and four discrete outputs, labeled as A, B, C, and D. Outputs A and C were designed to be used as the main stereo left/right outputs. The other two outputs, B and D, are implemented in some programs for use as quadraphonic reverb.
	The UAD Lexicon 224 fully models the individual sonics of all four outputs when available in the program algorithm. The alternate B and D outputs are available via the Rear Outs control (page 209).
	Note: The dry signal at the Lexicon 224 output is completely unprocessed.
Mono/Stereo Operation	The Lexicon 224 hardware has dual channel inputs (left and right) and is a true stereo processor. Like the hardware, when the UAD Lexicon 224 plug-in is used in a stereo-in/stereo out configuration, the left and right channel signals are both processed.
	When used in a mono-in/stereo out configuration, the mono input is sent to both channels of the stereo processor.

When configured as mono-in/mono-out ("MIMO"), output A is used exclusively except in programs 2, 4, and 9, where outputs A and C are summed into one monophonic signal. This implementation is recommended in the original hardware manual. If Rear Outs is enabled in MIMO mode, outputs B and D are used instead of A and C. See Table 17 on page 217 for a list of outputs used with each program in this configuration.

Primary & Hidden Controls The primary controls (those that are most typically used) are on the main "remote control" panel interface. Additional (less typically used) controls are available in a hidden control panel. The hidden control panel (Figure 66 on page 212) is accessed by clicking the "OPEN" text label to the right of the Display Panel.

For detailed descriptions of all parameters, see "Primary Controls" on page 205 and "Hidden Controls" on page 212.

Parameter Ranges & Default Values The parameter value ranges, default values, and availability of particular parameters within a given program may vary depending on which program is active. Parameter ranges are listed in the individual control descriptions. Default parameter values for each program are listed in Table 18 on page 217.

Note: Extreme parameter settings can cause Lexicon 224 to self-oscillate or cause other unexpected sounds. This behavior is identical to the original hardware.

Display Panel The Lexicon 224 display panel (Figure 64 below) consists of four display elements: Numerical Value, LED Value, Stereo Level Meters, and Overflow indicator. Exactly what is displayed here is dependent on the parameter being edited (if any) and the state of the Display Hold switch (page 214).

Figure 64. The Lexicon 224 Display Panel

Numerical Value

The three-character Numerical Value Display shows the value of parameters as they are being edited. The value of the edited parameter is displayed for 1.5 seconds unless the Display Hold switch is set to infinite, in which case the last edited parameter value continues to be displayed. If Display Hold is set to 1.5 (the default value), after parameters are edited, the value displayed here reverts after 1.5 seconds to a reverb time which is related to the combined Bass and Mid slider values. This relationship is based on approximations designed by the original Lexicon engineers; the actual decay times may not match the displayed value.

Value LED

The Value LED shows the units of the numerical value being displayed for a particular control. For parameters in the time domain, the "sec" (seconds) or "ms" (milliseconds) LED is lit. For parameters in the frequency domain, the "Hz" (Hertz) or "kHz" (kilohertz) LED is lit. For parameters that have no units value (e.g., Dry/Wet Mix), the value LED does not illuminate.

LED Meters

The six-segment LED meters display the left and right signal input levels at the Lexicon 224 analog-to-digital converters, which are fully modeled. The Meter LEDs indicate levels at –24 dB, –18 dB, –12 dB, –6 dB, and 0 dB. When the 0 dB LED illuminates, input clipping has occurred.

Overflow LED

The Overflow LED illuminates when an arithmetic processor overflow has occurred. Overflows can happen when loud signals are present at the input, when reverb decay times are long, and/or when self-oscillation occurs. Unexpected sonic artifacts and/or ringing can occur when the processor overflows.

Overflow behavior in the hardware is fully modeled in the plug-in. If processor overflows are causing undesirable sounds, overflow can usually be eliminated by reducing the levels with the Input controls, or by reducing the value of the Bass, Mid, and/or Treble Decay controls.

Primary Controls

Program

The Program buttons (Figure 65) are used to specify which of the nine default Lexicon programs, and its associated algorithm, is active. See "Lexicon 224 Programs" on page 201 for an overview.

Eight reverb programs and one chorus program are available. Click a reverb program button 1 – 8 to select that program. To select the chorus program, shift+click any program button, or click the CLK=CHORUS text label. The program button LED indicates which program is active except in chorus mode, when all eight program button LEDs are illuminated.

Figure 65. The Lexicon 224 Program Buttons

When a program is loaded, the original default Lexicon "recommended" factory settings for that algorithm are also loaded at the same time, overwriting previous settings (except when Immediate mode is active; see page 208 for details). Program settings can then be adjusted to taste using any available controls.

"Program Descriptions" on page 215 contains details about each program.

Important: If the program is changed when Immediate mode is disabled, settings from the previously selected program are lost. To retain custom program settings for future use, save the settings as a plug-in preset by using the UAD Toolbar or host application preset management techniques.

Reverb Time Reverb Time is the duration of the decay of the reverberant sound (the "reverb tail"). The reverb tail time is separated into two frequency component bands, Bass and Mid. The separation frequency of the two bands is defined by the Crossover control.

Bass	The Bass slider defines the reverb decay time for the frequencies below the Crossover value. Higher Bass values result in longer bass frequency decay times (when Crossover is not set too low). The Bass reverb decay time value, in seconds, is shown in the Numerical Display. The available range is 0.6 sec- onds to 70 seconds.
	This control works in conjunction with the Crossover parameter, which defines the range of the bass frequencies affected by the Bass control. Therefore ad- justing Bass may have little audible effect if Crossover is set to a very low value.
Mid	The Mid slider defines the reverb decay time for the frequencies above the Crossover value. Higher Mid values result in longer high frequency decay times (when Crossover is not set too high). The Mid reverb decay value, in seconds, is shown in the Numerical Display. The available range is 0.6 seconds to 70 seconds.
	Mid works in conjunction with the Crossover parameter, which defines the range of high frequencies affected by the Mid control. Therefore adjusting Mid may have little audible effect if Crossover is set to a very high value.
	Mid is a slightly misleading label, because this control actually affects the reverb decay for all frequencies above the Crossover value (not just the midrange). However, because the "highs" in the reverb can be rolled off with the Treble Decay control (and usually are), the midrange frequencies are often more prominent than a full-range tail.
Crossover	This control defines the crossover frequency (the split point) between the bass and upper frequency bands in the reverb tail. Higher Crossover values make the Bass parameter control a wider range of frequencies. Conversely, lower values make the Mid parameter control a wider range of frequencies. The available range is 100 Hz to 10.9 kHz.
	Crossover affects the reverb decay because it works in conjunction with the Bass and Mid reverb time parameters, which both define the length of the re- verb tail (one control for each frequency band). If those parameters are set to very short times, the result of adjusting Crossover may be very subtle.
	Note: Crossover will have no apparent effect if Bass and Mid are set to the same value.

Treble Decay Treble Decay sets a frequency above which decay is very rapid. Lower values will produce a "darker" reverb with less high frequency content. If Treble Decay is set very low, then adjusting Bass, Mid, and Crossover may have little to no audible effect. The available range is 100 Hz to 10.9 kHz.

Tip: Treble Decay adjusts the AMOUNT of reverb tail highs, while Mid adjusts the TIME.

Depth Depth sets the apparent distance between a source and its reverb, much like the positioning of microphones in an echo chamber. As the value is increased, the apparent distance from the source increases. The available range is 0 – 71, with zero being "close" and 71 being "far" (the numbers are arbitrary). The default value is program dependent.

Note: Depth is not available in P9 Chorus A. In this program the display is not updated when the Depth slider is moved.

Diffusion In most programs, Diffusion affects how quickly the echo density in the reverb builds up over time. In the original hardware, this parameter was usually referred to as "Shift-Depth" (changing the diffusion value required holding down the shift button while adjusting the depth amount).

Click the left ("<") decrement button to decrease the Diffusion value; click the right (">") increment button to increase the value. The available range is 0 – 63 (the numbers are arbitrary). The default value is program dependent; Table 18 on page 217 lists the default values for each program.

Note: Diffusion is unavailable in P4 Acoustic Chamber.

Zero is the least dense setting. Density increases as the Diffusion value is increased, but setting Diffusion higher than 40 can actually sound less dense. The fastest density buildup is achieved with Diffusion values near the middle of the range (approximately 32-37). Higher Diffusion values are frequently desirable when the material has a lot of percussion. Higher Diffusion can also contribute to a smoother-sounding reverb. With low Diffusion values the early reverb will be "grainy" and sparse, but will produce a clear, bright sound that is very useful with strings, horns, and vocals. Low Diffusion is also useful in classical music or in adding a sense of depth to an overall mix. Note that in Lexicon 224, lower frequencies are generally less diffuse.

Note: If Immediate mode is active, the Diffusion value is retained when changing programs.

Predelay Predelay produces a short delay between the sound source and the onset of reverberation. Higher Predelay values increase the time before reverb onset. The range of this parameter varies depending on the active program; see Table 16 on page 208 for the available values. The default value is program dependent.

Program	Predelay Range	Program	Predelay Range
1. Small Concert Hall B	24 - 152	6. Small Concert Hall A	24 - 152
2. Vocal Plate	0 - 107	7. Room A	24 - 255
3. Large Concert Hall B	24 - 152	8. Constant Density Plate A	5 - 185
4. Acoustic Chamber	25 - 255	9. Chorus A	0 - 253
5. Percussion Plate A	0 - 107	Note: Predelay values are in	milliseconds.

Table 16. Lexicon 224 Predelay Ranges

Immediate

When Immediate ("IMMED") is enabled, current parameter values are retained when a new program is selected. When Immediate is inactive and a program is selected, the Lexicon default factory preset parameter values for the program are loaded and the control sliders move to the preset values.

Enabling Immediate mode is convenient for quickly auditioning the various program algorithms using the same "persistent" parameter values. Disabling Immediate mode is convenient for quickly auditioning the various programs with the Lexicon factory default settings.

The default Immediate value is OFF. Immediate affects the following parameters: Bass, Mid, Crossover, Treble Decay, Depth, Predelay, Diffusion, Mode Enhancement, Pitch Shift, Decay Optimization, and Rear Outs. **Important:** When Immediate is off and a program is changed, previously modified parameter values are lost, unless the settings were saved as a preset or if the session file was previously saved so it can be recalled.

System Noise This UAD-only control enables or disables the modeled inherent dynamic system noise of the original Lexicon 224 hardware. Disabling System Noise enables a more modern-sounding (i.e., cleaner) 224. Click the button to toggle the state; System Noise is active when the button LED is lit. The default state is ON.

The elements of the modeled System Noise include quantization effects (at input A/D, output D/A, and within the algorithm), zipper/stepping noise when adjusting parameters, transformer distortion, and the quiescent noise floor.

Zipper/stepping noise when adjusting parameters can be defeated by disabling System Noise. However, zipper/stepping noise in delay modulation (i.e., Mode Enhancement) can only be reduced, but not completely defeated, by disabling System Noise.

Note: System Noise is a global (per instance) parameter; its state does not change when different programs are selected.

Rear Outs The Rear Outs control is available to select the alternate pair when the algorithm has alternate sonics at outputs B and D. See "Inputs & Outputs" on page 202 for an overview of the hardware implementation.

Rear Outs Notes

- The left/right outputs of the plug-in always reflect hardware outputs A and C respectively when Rear Outs is inactive, and outputs B and D respectively when Rear Outs is active.
- Outputs A and C are "recommended" for stereo use (the rear outs are generally not used in typical applications).
- Outputs A and C are identical to D and B respectively in the following programs: P2 Vocal Plate A, P5 Percussion Plate A, P8 Constant Density Plate A, and P9 Chorus A. Consequently, the Rear Outs control effectively swaps the left/right outputs in these programs.

Mode Enhancement

Mode Enhancement makes the sound of the Lexicon 224 programs more natural by preventing room modes from ringing in the reverb tail. Mode Enhancement works by continuously modulating certain delay lines (taps) within the program algorithms, which increases the effective density without thickening the reverb itself.

Mode Enhancement is factory-optimized for each program and should not require adjustment in typical use. For this reason, it was deliberately made difficult to access in the original hardware. However, creative use of the parameter is encouraged by making it easier to access in the plug-in.

Mode Enhancement has three control elements: Enable, Amount, and Pitch Shift. As in the original hardware, lower values of Mode Enhance Amount and higher values of Pitch Shift increase "movement" and make the result more prominent.

Note: The Mode Enhance Amount and Pitch Shift controls have no effect unless the Mode Enhance Enable control is active.

Mode Enhance Enable

MODE (ENH This button enables or disables Mode Enhancement for the active program. Mode Enhancement is active when the button LED is lit. The default state is ON for all programs.

Tip: This control, just as with the original hardware, resets the algorithm. Therefore Mode Enhance Enable can be used to quickly "kill" the reverb tail while staying in the same program.

Mode Enhance
AmountThese two adjacent buttons control the amount of Mode
Enhancement, or technically speaking, the amount of
time between delay line updates. Click the left ("<") but-
ton to decrement the value; click the right (">") button to
increment the value. The available range is 1 through
16. Lower values increase the effect.

Mode Enhance Pitch Shift

Pitch Shift is a secondary parameter of Mode Enhancement that controls the size of the delay line update steps. Lower values produce smaller steps, while higher values produce larger

steps. Click the left ("<") button to decrement the value; click the right (">") button to increment the value. The available range is 1 through 16. Higher values increase the effect.

The Pitch Shift controls are accessed in the Hidden Controls panel. See page 212 for access details.

Decay Optimization Decay Optimization improves the Lexicon 224 reverb clarity and naturalness by dynamically reducing reverb diffusion and coloration in response to input signal levels. However, if set too high, it can make the decay less even. Decay Optimization has two control elements: Enable and Amount.

> Decay Optimization is factory-optimized for each program and should not require adjustment in typical use. For this reason, it was deliberately made difficult to access in the original hardware. However, creative use of the parameter is encouraged by making it easier to access in the plug-in.

Decay Optimize Enable

This button enables Decay Optimization for the active program. Decay Optimization is active when the button LED is lit. The default state is ON.

Note: Decay Optimization is unavailable for P8 Constant Density Plate A and P9 Chorus.

Decay Optimize Amount These two adjacent buttons control the amount of Decay Optimization. Click the left ("<") button to decrement the value; click the right (">") button to decrement the value; click the right (">") button to increment the value. The available range is 1 through 16. As in the original hardware, lower values make the result more prominent.

Note: The Decay Optimization Amount controls have no effect unless the Decay Optimization Enable control is active.

Mix Controls

The Dry, Wet, and Solo parameters control the effect mix in the plug-in. These controls are not available in the original hardware.

Note: The Mix controls are global parameters; their state does not change when different programs are selected.

Solo When Solo is activated, the Dry/Wet mix is set to 100% wet and the Dry/Wet controls are deactivated. Solo mode is optimal when using Lexicon 224 in the "classic" reverb configuration (placed on an effect group/bus that is configured for use with channel sends). When Lexicon 224 is used on a channel insert, Solo should be deactivated. The default state is ON.

Note: Solo is a global (per Lexicon 224 plug-in instance) control.

Dry/Wet These two buttons control the balance between the reverb processor and the source signal when Solo mode is inactive. Click the DRY button to reduce the reverb amount; click the WET button to increase the reverb amount.

The Dry/Wet mix is indicated in the Numerical Display as a percentage. A value of 50 produces an equal blend of the wet and dry signals. Values greater than 50 emphasize the wet signal, and values less than 50 emphasize the dry signal.

Clicking the DRY button once will decrement the value by one percent; clicking WET once will increment the value by one percent. To increase the fine resolution when adjusting these controls, hold SHIFT (on the computer keyboard) when clicking the controls. Shift+click will decrement (DRY) and increment (WET) by a value of 0.1 percent instead of one percent.

The Dry/Wet controls are typically used when Lexicon 224 is inserted on individual channels. When Lexicon 224 is used on a group/bus in a typical reverb send/return configuration, set to 100% WET or activate SOLO mode.

Hidden Controls

Additional UAD controls are available in a hidden control panel. Refer to Figure 66 in parameter descriptions.

Figure 66. The Lexicon 224 Hidden Controls

Access	The hidden controls are exposed by click-
	ing the "OPEN" text to the right of the Dis-
	play Panel. Conversely, the exposed
	panel is closed by clicking the "CLOSE"
	text while the panel is open.

Note: The last-used state of the Hidden Controls panel (open or closed) is retained when a new Lexicon 224 plug-in is instantiated.

Pitch Shift Pitch Shift is a component of Mode Enhancement. See "Mode Enhance Pitch Shift" on page 210 for parameter details.

Input Gain The independent left ("L") and right ("R") Input Gain parameters control the signal levels at the input to the reverb processor. They do not affect the dry signal, so Input Gain can be used to adjust the wet/dry mix. The default value is 0 dB. The available range is ±12 dB. The right channel control is unavailable when Lexicon 224 is used in a mono-in/mono-out configuration.

As signal levels into the Lexicon 224 increase, the analog and digital response of the device becomes increasingly nonlinear. If signals are too high, the Lexicon 224 A/D inputs and/or processor can overload, lighting the Overflow LED and causing sonic artifacts. See "Overflow LED" on page 204 for more information.

Tip: Click the text label ("Input Gain") to return the value of both channels to zero.

Output Level The independent left ("L") and right ("R") Output Level parameters control the signal levels at the output of the plug-in. The default value is 0 dB. The available range is $-\infty$ (infinite) dB to +12 dB. The right channel control is unavailable when Lexicon 224 is used in a mono-in/mono-out configuration.

Tip: Click the text label ("Output Level") to return the value of both channels to zero.

Link Link/unlink allows the left and right controls for Input Gain and Output Level to be unlinked (non-ganged) in order to apply a different value for each channel. Link is inactive when the LED is unlit. Click the Link LED to toggle the state. The default state is ON. If the left and right controls have different values when link is inactive and Link is engaged, the left channel value is copied to the right channel (thereby overwriting the right channel value).

When Link is active, automation data is written and read for the left channel only. The automation for the left channel controls both channels in Link mode.

Note: When link is active, modifying the right channel parameters will have no effect when changed from a control surface or when in "controls only" (non-GUI) mode.

Bug Fixes The original Lexicon 224 code contains programming errors in the Hall B and Chorus algorithms. These computer code bugs can cause incorrect Bass decay times (Hall B programs) and undesirable "pops" and/or "thumps" in the right channel (Chorus program) with certain source signals and parameter configurations.

The bugs have been corrected in the UAD implementation of the plug-in, but we have provided the option of using the original code for the sake of pure authenticity.

The UA logo is actually a switch. When the UA logo is illuminated, the source code bugs are fixed. The default state is ON. Click the UA logo to disable the UA bug fixes and revert to the original hardware behavior.

Display Hold

The Display Hold switch alters the behavior of the Numerical Display (page 203). In the original hardware, the values of parameters that are being modified are displayed for 3 seconds before reverting back to displaying the average decay time.

The Hold switch changes this behavior. When set to infinite (" ∞ "), the Numerical Display will continue to show the last modified parameter value. When set to infinite and a program is changed, the average decay time is displayed until a parameter is modified.

Note: The last-used state of the Display Hold parameter is retained when a new Lexicon 224 plug-in is instantiated.

PowerThe Power switch is a bypass control. Click the switch to change the
Power state. When bypassed, plug-in processing is disabled, and the
Display Panel and all button LEDs are dimmed.

Program Descriptions

P1 Small Concert Hall B	This program emulates the sound of a small concert hall, with moderate initial density and moderately non-uniform decay. It is optimized for reverb times of 1.5 to 5 seconds (for longer decay times, P3 Large Concert Hall B is recommended instead). The most natural sound is obtained when Bass and Mid are relatively close to the same setting. This program uses the exact same algorithm as P3 Large Concert Hall B.
P2 Vocal Plate	This is a plate reverb emulation optimized for voice. It has low initial density and coloration, resulting in a clear, bright sound. This program uses the exact same algorithm as P5 Percussion Plate A, but with slightly different inherent diffusion.
P3 Large Concert Hall B	This program emulates the sound of a large concert hall, with low density and minimal coloration. It is optimized for long reverb times. With percussive sounds, increasing the diffusion value is recommended. This program uses the exact same algorithm as P1 Small Concert Hall B.
P4 Acoustic Chamber	This program sounds like a chamber, but with less initial density. It tends to sound best with shorter reverb times (2 to 5 seconds). The most chamber-like sound is obtained with Depth at a value of zero. Diffusion is preset in this pro- gram and cannot be modified. Unlike all other Lexicon 224 programs, this al- gorithm has monophonic input.
P5 Percussion Plate A	This is a plate reverb emulation optimized for percussive sounds. It has high initial density and coloration, and sounds best with shorter reverb times. This program uses the exact same algorithm as P2 Vocal Plate, but with slightly dif- ferent inherent diffusion.
P6 Small Concert Hall A	This program is similar to P1 Small Concert Hall B, except it is brighter overall and the Treble Decay control is more gentle. The original hardware manual recommends equalizing this reverb return about +3 dB below 200 Hz to "add to the richness and naturalness of the reverb."
P7 Room A	Program 7 is a room simulator with moderate to high initial density and low to moderate coloration. It sounds great on speech and many types of music. This program presents an especially wide output when used with a stereo in- put source.

P8 Constant Density Plate A In naturally occurring reverb, new reflections are continuously added to the decaying sound over time. This sonic build-up increases density and coloration in the reverb tail. P8 Constant Density Plate A has high initial density and coloration (giving a "plate" type of sound), however the density does not increase over time and remains inherently constant. This can result in less "swoosh" in the reverb tail and provides another creative option. Decay Optimization and true stereo input are unavailable in this program (inputs are always summed to mono, even in stereo-in/stereo-out configurations).

P9 Chorus A The Chorus A program is an eight-voice chorus with four voices on each stereo channel. Each voice has a time delay which varies randomly and independently, resulting in a thick, rich sound.

When Chorus is active, each of the first four sliders controls the gain level for a stereo pair of voices. The sliders are linear faders, not log faders, so the default positions of all four sliders (about 1/2 way up) correspond to gains 6 dB below maximum.

The first two voice pairs have overlapping delay ranges. Phasing/flanging effects can be achieved by setting their gains to similar levels. Phasing/flanging can also be achieved (with a mono or centered input) when the left and right channels are mixed together, such as when used in a mono-in/mono-out configuration.

The Diffusion control is active in this program. Diffusion acts upon the third and fourth pair of stereo voices, producing a cluster of tightly spaced echoes whose shape is governed by the Diffusion control. The Lexicon 224 is one of the few processors that has diffusion on chorus voices; this feature is a primary factor in its distinctive character.

Note: The Bass, Mid, Crossover, and Treble Decay behaviors are unavailable in P9 Chorus A. Instead, each of these sliders controls the level of a stereo voice pair.

MIMO Program Outputs When Lexicon 224 is used in a mono-in/mono-out ("MIMO") configuration, the hardware outputs that are used for the plug-in are listed in Table 17 on page 217. These software assignments are per the guidelines in the original hardware manual and cannot be modified.
Program	Output(s)	Program	Output(s)
1. Small Concert Hall B	A	6. Small Concert Hall A	А
2. Vocal Plate	A + C	7. Room A	А
3. Large Concert Hall B	A	8. Constant Density Plate A	А
4. Acoustic Chamber	A + C	9. Chorus A	A + C
5. Percussion Plate A	A + C		

Table 17. Lexicon 224 Outputs Used With Monophonic Output

Default	Table 18 below lists the default values of all available parameters for each
Parameter Values	program.

Table 18. Lexicon 224 Default Parameter Values

Program	Bass	Mid	Crossover	Treble Decay	Depth	Diffusion	Pre- delay	Enhance	Pitch Shift	Decay Opt.
1. Small Concert Hall B	3.0	2.0	540Hz	4.40	23	21	024	02	01	05
2. Vocal Plate	2.2	2.2	1kHz	10.9	00	04	000	02	01	05
3. Large Concert Hall B	3.4	2.6	540Hz	4.00	21	01	024	02	01	05
4. Acoustic Chamber	2.8	2.2	1kHz	6.60	00	N/A	025	02	01	05
5. Percussion Plate A	2.2	2.2	1kHz	10.9	00	37	000	02	01	05
6. Small Concert Hall A	3.0	2.0	540Hz	6.60	23	28	024	02	01	05
7. Room A	1.8	1.8	540Hz	4.40	23	24	024	02	02	05
8. Constant Density Plate A	1.8	1.8	540Hz	10.9	23	37	005	07	01	N/A
9. Chorus A	N/A	N/A	N/A	N/A	N/A	22	012	02	02	N/A

Lexicon 224 Latency The Lexicon 224 uses an internal resampling technique to facilitate its sonic quality. This resampling results in a slightly larger latency than other UAD plug-ins. See "Upsampled Plug-Ins" on page 563 for more information.

CHAPTER 21 Little Labs IBP

Overview

The Little Labs IBP Phase Alignment Tool easily eliminates the undesirable hollow comb-filtered sound when combining out-of-phase and partially out-of-phase audio signals. Designed as a phase problem-solving device, the award-winning Little Labs IBP ("In-Between Phase") has established itself with audio engineers as not only a "fix it" tool, but as a device for manipulating audio phase as a creative, tonal color tool as well. Whether combining direct and microphone signals, acoustic guitar and vocal mics, drum kit mics, or multiple split-guitar amps, the recorded audio signal phase can be quickly and easily controlled with the Little Labs IBP Phase Alignment Tool.

Little Labs IBP Screenshot

Figure 67. The UAD Little Labs IBP plug-in window

Little Labs IBP Controls

All parameters are clearly labeled with control names. Please refer to Figure 67 on page 218 for control descriptions.

Delay Adjust The Delay Adjust parameter is unique to Universal Audio's "workstation" version of the Little Labs IBP. Delay Adjust is a continuously variable control that simply delays the input signal from 0.0 to 4.0 milliseconds.

Unlike the "analog" Phase Adjust parameter, which is frequency dependent, Delay Adjust is purely "digital" and shifts all frequencies equally. Delay Adjust accomplishes the same function as manually moving an audio region forwards in the timeline so it plays back a little later in relation to other regions.

- Delay AdjustThis switch bypasses the Delay Adjust parameter. Delay Adjust is bypassedBypasswhen the switch is engaged (darker).
- **Phase Adjust** Phase Adjust is the main parameter in the Little Labs IBP. It is a continuously variable control that shifts the phase of the input signal. The range of Phase Adjust is either 90° or 180°, dependent on the Phase Adjust 90°/180° switch.

The Little Labs IBP hardware is an all-analog device that uses analog allpass filters to produce phase shifting. Allpass filters displace signals in time as a function of frequency (they are frequency dependent). The modeled UAD version accurately models the hardware along with all its idiosyncrasies.

Therefore phase shifting using the Phase Adjust knob is not "perfect" like mathematically-manipulated signals in the digital domain. When Phase Adjust is set to 180° on one of two identical tracks side-by-side, the signals will not cancel as you may expect.

Note: If a "standard" 180° phase shift is desired, use the Phase Invert switch. If "digitally pure" frequency-independent phase shift is desired, use the Delay Adjust parameter.

Phase AdjustThis switch bypasses the Phase Adjust parameter. The signal phase is normal
when the switch is engaged (darker).

Phase Invert This switch inverts the polarity of the input signal, like the phase button on a mixing console. Phase is inverted when the switch is engaged (darker).

Phase Adjust 90°/180°	This switch determines the range of the Phase Adjust parameter. This is useful when finer Phase Adjust resolution is desired.
	When the switch is disengaged, the Phase Adjust range is 180°. When the switch is engaged (darker), the Phase Adjust range is 90°.
Phase Center Lo/Hi	This switch sets the range of frequency emphasis. When the switch is disen- gaged (lighter), the Phase Center range is Hi. When the switch is engaged (darker), the Phase Center range is Lo.
	Note: Use of the 90°/180° and Lo/Hi parameters are typically used for in- dividual tone signals such as a kick drum or toms as opposed to program ma- terial.
Power	This switch disables the plug-in. When the switch is disengaged, the plug-in is bypassed. When the switch is engaged (darker), the plug-in is active and the green LED is illuminated.

Little Labs IBP Latency

The Little Labs IBP uses an internal upsampling technique. This upsampling results in a slightly larger latency than other UAD plug-ins. See "Upsampled Plug-Ins" on page 563 for more information.

Note: Compensating for Little Labs IBP is not required if the host application supports full plug-in delay compensation throughout the signal path, or when it is used only on the outputs.

CHAPTER 22

Little Labs VOG

Bass Resonance Processor

For many top engineers, the Little Labs VOG (Voice Of God) is the ultimate bass resonance tool for mixing. Available for the first time as a plug-in, the Little Labs-authenticated VOG for the UAD-2 platform accurately models the sonic characteristics of this unique 500-series hardware audio processor in every detail. The VOG is used to accurately target and accentuate low frequency material, from vocals to bass guitar and drums — adding both heft and precision beyond a simple EQ. Put simply, it's like a magnifying glass for the bottom end of your mixes.

One of the most important components of any good mix is blending the low frequencies together in such a way that they don't conflict. No matter what style of music you make – from rock to reggae, to hip-hop to hardcore – few tools are as easy to use and effective as the popular Little Labs VOG.

History Little Labs has a knack for creating problem-solving tools for the studio that perform equally well as creative coloration effects and tone-boxes. The original collaboration between UA and Little Labs saw the release of the UAD Little Labs IBP plug-in — widely recognized as one of the most versatile phase correction plug-ins available today. Continued collaboration between Universal Audio and Little Labs now provides another instant studio classic, the VOG.

Upon its introduction in 2009, owners of the hardware VOG quickly realized multiple units are a must have — one for bass, kick drum, toms, low frequency percussion, and especially vocals. Fortunately, with the Little Labs VOG plug-in for the UAD-2, customers can have as many instances as they need to make "the low end" come to life.

Little Labs VOG Screenshot

Figure 68. The UAD Little Labs VOG plug-in window

Operational Overview

Two simple knobs allow you to dial in the VOG's desired frequency and effect amplitude. The center of the sweepable frequency range is selected via two push-buttons of 40 Hz and 100 Hz, or you can set the center to 200 Hz by pressing both buttons simultaneously. Everything below the targeted frequency peak is rolled off in a smooth curve — up to -24 dB per octave — ensuring that the low end is always tight and out of the mud, while the frequency

cies above remain intact. The higher the amplitude of the peak resonance frequency, the more you cut off the mud below, effectively performing two functions at once. A dedicated "flat" button allows you to quickly audition A/B comparisons.

In Use The VOG is intended for mixing, mastering, post-production sweetening, sound design, and audio restoration. Use it to easily simulate proximity effect for adding chest resonance and "heft" to vocals. Simple adjustments will also yield enormous sounding drums — just like tweaking the tension of a drumhead. Or, completely transform the tonal characteristics of electric bass tracks — for example, go from a solid body sound to a chambered body sound in seconds. The VOG's flexibility makes it the right choice on a wide range of musical sources; it's the perfect way to tune the low end of any mix for incredible detail and punch.

Stereo Functionality Unlike the original hardware (which is monophonic), the plug-in enables stereo use with one control set, providing perfectly matched stereo response. When the plug-in is used in mono-in/stereo-out and stereo-in/stereo-out configurations, the controls affect both the left and right signals.

Little Labs VOG Parameters

Amplitude

Amplitude adjusts the amount of the effect. Increasing the control boosts the gain of the frequencies determined by the Frequency and Center controls.

amplitude

0 – 10, are arbitrary and do not reflect a particular dB value.

Note: The control values for Amplitude, which range from

Frequency

This control adjusts the target frequency of the effect. Frequencies above the current setting are boosted by the amount set with the Amplitude control. Frequencies below the current setting are attenuated by -24 dB per octave.

The available frequency range is determined by the Center button settings, and are shown in Table 19 on

page 224.

Like the original hardware, increasing the Frequency value (rotating clockwise) actually *lowers* the target frequency ("increases the low end"). Changes to this setting are heard only if Amplitude is set above zero.

Note: The control values for Frequency, which range from 0 – 10, are arbitrary and do not reflect a particular frequency value.

Center The two Center switches define the active center frequency of the effect, which in turn determines the available frequency range. The four available center frequencies, and resulting frequency ranges, are shown in Table 19 below.

A switch is "ON" when its LED is red. A green LED indicates the switch is "OFF."

Table 19. Center Switch Frequency Values

"40" Button LED	"100" Button LED	Center Frequency (Hz)	Frequency Range (Hz)
Green	Green	40	18 – 60
Red	Green	42	20 - 62
Green	Red	100	50 – 180
Red	Red	200	100 – 305

Flat

The EQ circuitry is bypassed when Flat is enabled (red LED); the circuit is active when Flat is disabled (green LED). When Flat is on, the dry signal path of the hardware is still

being modeled and DSP is used. For true bypass, use the Power switch.

Power

Power is the plug-in bypass control. When set to OFF, emulation processing is disabled, the LEDs are dimmed, and DSP usage is reduced (if UAD-2 DSP LoadLock is dis-

abled). Power is useful for comparing the processed settings to the original signal.

The Little Labs VOG hardware unit

CHAPTER 23 Manley Massive Passive EQ

Overview

Universal Audio's UAD Powered Plug-In versions of the Manley Massive Passive EQs represent UA's most ambitious and detailed EQ model to date. The two-channel, four-band Manley Massive Passive tube EQ utilizes design strengths from choice console, parametric, graphic, and Pultec EQs — delivering a fundamentally different sounding EQ that is beyond compare. The incredibly natural, organic results of the Manley design method — evidenced on albums such as Wilco's Yankee Hotel Foxtrot, Amon Tobin's Foley Room and Tori Amos' A Piano: The Collection — demonstrate how the Massive Passive's natural treatment of a signal lends itself to both radical tonal shaping as well as delicate vocal shading or subtle mastering enhancement.

Painstakingly modeled over a six-month period, and rigorously scrutinized for authenticity by Manley's engineering team, Universal Audio's standard and mastering versions of the Massive Passive EQ plug-in are included. Both capture the behavior of the original hardware; from the unusual filter curves, to the multiple band interdependencies, right down to the tube amplifier distortion, and all-important transformer/inductor hysteresis.

"Passive" refers specifically to the tone shaping elements of the equalizer, which use only resistors, inductors, and capacitors to create all frequency changes. The Massive Passive utilizes older parallel concepts rather than non-interactive series designs as defined by George Massenburg's original parametric EQ. The Frequency controls intentionally interact with one another, as do the Gain and Bandwidth controls. While this may result in the appearance of some unorthodox knob positions, it is specifically these band interdependencies between all bell, shelf and cut filters that allow for the Massive Passive's natural and organic sound.

Massive Passive Screenshots

Figure 69. The Massive Passive plug-in window

Figure 70. The Massive Passive Mastering plug-in window

Unusual EQ Conventions

The Massive Passive has design and operation characteristics that make it unique in the EQ world. Some of these factors mean the "Massivo" may not respond in a manner that you would expect from typical EQs. Keeping these points in mind may help you obtain more satisfactory results. See "Notes from Manley Laboratories" on page 236 for more tips.

- Passive EQNo active components are used in the EQ circuits, just like revered vintage
EQs. This can make some adjustments respond in more subtle ways.
- ParallelThe EQ bands are routed in parallel instead of serially, so gain values for the
bands don't "add up" like most EQs. For example, if two bands in the same
channel are boosted 20 dB at 2.7kHz, you'll get much less than 40 dB of
boost at 2.7kHz.

- **Unique Shelves** Most EQs offer a shelving mode for the edge bands only. Massive Passive offers the shelving option on all bands for expanded sonic possibilities, such as "staircase" EQ curves.
- **No negative** feedback loops One result of not using negative feedback loops in the design is that the gain control for a band cannot have a "bipolar" boost and cut control. Only band gain is available; how that band gain is applied, either as a boost or as a cut, is specified with a separate toggle switch.
- **Control** Interaction Due in large part to the above points, the Massive Passive controls are much more interactive with, and interdependent upon, each other. We encourage experimentation with an open mind, without expectations of what a visual interpretation of what control settings "should" do.

Massive Passive Mastering EQ

Manley Labs developed the Massive Passive Mastering EQ to better address the specific needs of mastering engineers. Your UAD Massive Passive license includes both the standard and mastering versions, available as two individual plug-ins.

The Massive Passive Mastering has nearly the same features and control set (plus all the musicality of) the standard version with a few tweaks that offer more practical functionality for program material. The Mastering version features include:

- Stepped channel gain, band gain, and bandwidth controls for repeatability.
- Channel gain and band gain ranges are reduced for finer resolution.
- Low/high pass filter frequencies and slopes are optimized for mastering.

The Mastering Massive Passive is identified by the all-black "flat top" band gain and bandwidth control knobs and the word "MASTERING" near the center of the interface (Figure 70 on page 227).

Standard vs. Mastering Versions

The layout and function of the Massive Passive controls are essentially identical for both the Standard and Mastering versions. The exact control differences between the controls are detailed in Table 20 below.

	Standard	Mastering	
Channel Gain Range	-6 dB to +4 dB	±2.5 dB (0.5 dB steps)	
Band Gain Range	±20 dB	±11dB (16 steps)	
High Pass Filter Values (Hz)	22, 39, 68, 120, 220	12, 16, 23, 30, 39	
Low Pass Filter Values (kHz)	6, 7.5, 9, 12, 18	15, 20, 27, 40, 52*	
Low Pass Filter Slope	18 dB/oct (6K, 7K5, 9K) 30 dB/oct (12K) Modified Elliptical (18K)	18 dB per octave* (*30 dB/oct @ 52K)	
Channel Gain, Band Gain, Bandwidth	Continuous	Stepped	

Table 20. Control differences between Massive Passive versions

Massive Passive Band Controls

Massive Passive has two identical channels (left and right). Each channel has four EQ bands, with five controls in each band.

Because both UAD Massive Passive plug-ins operate the same way (and the bands of each channel are identical), the control descriptions for each band are only detailed once.

Important: See "Standard vs. Mastering Versions" on page 229" for the exact differences between the Massive Passive parameters.

Boost/Cut/Out

This three-position toggle switch determines whether the frequency band will be boosted, cut, or disabled altogether. The amount of boost or cut to be applied to the band is determined by the Band Gain control.

When Boost or Cut is selected, its label illuminates (green for Boost, red for Cut). When the switch is in the OUT position, the band is disabled.

Note: When set to OUT, the other band controls have no effect.

Shelf/Bell The Shelf/Bell toggle switch defines the shape of the filter band. A unique aspect of this control is that unlike other EQs where only the edge frequencies offer a shelving mode, with Massive Passive all bands can be used in either mode for expanded sonic possibilities.

Note: The Bandwidth control (page 231) affects the slope of the band filters in both Shelf and Bell modes.

Shelf

The two lowest (leftmost) bands can each be in Low Shelf mode; the two highest (rightmost) bands can each be in High Shelf mode. Shelf slopes generally boost or cut towards the highs or lows (thus the high shelves and low shelves). The two middle shelves are almost the same as the outer ones but just have other (interleaved) frequency choices.

Bell

Bell curves focus their boost and cut at a given frequency (the "Frequency" on page 233) and the further away the signal is from that frequency, the less boost or cut is applied.

Band Gain

This control determines the amount of EQ gain to be applied to the band. The range is from zero gain (flat) at the fully counter-clockwise position, to the maximum value at the fully clockwise position. Whether the gain is applied as a boost or cut is defined by the Boost/Cut/Out switch (page 229).

The range for the standard version is continuously variable at up to ± 20 dB; the range for the Mastering version is up to ± 11 dB in 16 steps (in both ver-

sions the maximum value depends on the Bandwidth control).

Important: When Gain for the band is set to zero, the other band controls have no effect.

Unlike most EQs, this control is not flat at the center position with the gain cut or boosted by moving the control to left or right of center. This design allows the band gain to operate at twice the knob resolution as that of a "conventional" dual-purposed control, as well as facilitating a guicker and more accurate return to zero.

Gain has a fair amount of interaction with the Bandwidth control. The maximum band gain is available in Shelf mode when Bandwidth is fully counter-clockwise; less band gain is available in Shelf mode as the Bandwidth is decreased (rotated clockwise). Conversely, the maximum gain is available in Bell mode when Bandwidth is fully clockwise; in Bell mode less band gain is available as Bandwidth is decreased (rotated counter-clockwise).

Due to the parallel EQ topology, the four band Gain controls also interact with each other unlike typical EQs. For example, if two bands in the same channel are boosted 20 dB at 2.7kHz, you'll get much less than 40 dB of boost at 2.7kHz. This also implies that if you first boost one band, that the next three will not seem to do anything if they are at similar frequencies and bandwidths.

Bandwidth

Bandwidth adjusts the slope or "Q" of the band filter in both Bell and Shelf modes. Bandwidth does not have a lot of range and it also affects the maximum boost and cut (like a Pultec).

The widest Q (which is obtained at maximum boost or cut) is approximately 1 for the 22–1K (leftmost) band, and 1.5 for the other three bands. The narrowest Q is approximately 2.5 to 3 for all of the bands.

Bell Mode

In Bell mode, rotating the control counter-clockwise increases the bandwidth (lowers the Q) of the band and a broader range frequencies is affected. As Bandwidth is rotated clockwise, bandwidth is decreased (Q is increased) and a narrower range of frequencies is affected.

At the narrowest settings (Bandwidth fully clockwise), the maximum boost/cut gain of 20 dB is available. As Bandwidth is broadened, the available band gain is decreased, down to about 6 dB of boost/cut at the widest (fully counter-clockwise) settings. The effect of the Bandwidth control in Shelf mode is shown in Figure 71 on page 232.

Shelf Mode

In Shelf mode, rotating Bandwidth counter-clockwise decreases the slope of the shelf and Gain adjustments are more gentle. As Bandwidth is rotated clockwise, the shelf slope steepens, and Gain changes will be more obvious. As Bandwidth is increased in Shelf mode, a bell curve begins to be introduced in the opposite direction (i.e., overshoot). For example, if the Shelf is boosted, a dip is created at higher Bandwidth values. At maximum Bandwidth, this overshoot curve is pronounced. The effect of the Bandwidth control in Shelf mode is shown in Figure 72 below.

Figure 71. Effect of Bandwidth control on response curve in Bell mode

Figure 72. Effect of Bandwidth control on response curve in Shelf mode

Frequency

This control defines the center frequency (Bell mode) or edge frequency (Shelf mode) for the band. Each band provides a wide range of specially tuned overlapping and interleaving frequency choices. The available frequencies for each band are listed in Table 21 below.

Available Frequencies

Table 21. Available band frequencies (standard and mastering)

Massive Passive Band	Selectable Frequencies (Hz)	
Low	22, 33, 47, 68, 100, 150, 220, 330, 470, 680, 1K	
Low Mid	82, 120, 180, 270, 390, 560, 820, 1.2K, 1.8K, 2.7K, 3.0K	
High Mid	220, 330, 470, 680, 1K, 1.5K, 2.2K, 3.3K, 4.7K, 6.8K, 10K	
High	560, 820, 1.2K, 1.8K, 2.7K, 3.9K, 5.6K, 8.2K, 12K, 16K, 27K	

Channel Controls

The controls for the two identical channels (left and right) are detailed below. Because both UAD Massive Passive plug-ins operate the same way (and the controls for each channel are identical), the control descriptions for each channel are only detailed once.

Note: See "Standard vs. Mastering Versions" on page 229" for the exact differences between the Massive Passive parameters.

EQ In

The EQ In pushbutton switch enables the channel. When the button illuminates in a brighter blue, the channel is active and the other channel controls will affect the signal. When this control is disabled, all the desirable low-level system filtering and coloration is retained in the channel, just like the original hardware.

Channel Gain

This knob sets the overall gain for the channel. The range for the standard version is continuously variable from -6 dB to +4 dB. The range for the Mastering version is $\pm 2.5 \text{ dB}$, in 0.5 dB steps.

The Channel Gain controls are intended to help match levels between "Bypass" and "EQ enabled" modes so that the EQ effect can be more accurately judged. With drastic EQ there may not be enough range to match levels, but with drastic EQ this kind of comparison is of little use. The range is small to allow easier and finer adjustments.

- Filters Low Pass and High Pass filters are available for both channels. The response curves of the filters are shown in Figure 73 below. The available Filter values differ between the standard and mastering versions; see Table 20 on page 229 for the available values for each version.
- Low Pass The Low Pass filter allows the channel's lower frequencies to pass while attenuating higher frequencies. The slope of the Low Pass filter depends on the value set for the filter. At 6K, 7K5, and 9K values, the filter slope is 18 dB/octave. At these

values, a small (1.5 to 2 dB) bump occurs in the response before the curve drops off. At 12K, the slope is 30 dB/octave. At 18K, a modified elliptical filter is used.

In the mastering version, when Low Pass is set to 27kHz the frequency response is down by about 0.6 dB at 20kHz. When the control is set to 52kHz, there is actually a boost of about 0.4 dB at 20kHz; the filter is slightly resonant at this setting so there is a slight boost before the filter starts rolling off.

High Pass

The High Pass filter allows the channel's higher frequencies to pass while attenuating lower frequencies. The slope of the High Pass filter is 18 dB/octave.

Figure 73. High Pass and Low Pass filter response curves (standard version)

Mastering
FiltersThe Low Pass/High Pass filter frequencies in the mastering version are tuned
specifically for mastering, and the slopes are flatter until the knee. The slopes
are 18 dB per octave on the mastering filters except for the highest value
(52K) which is 30 dB/octave.

Other Controls

Power

The Power and Link controls are global to both channels.

Power is a two-state knob that determines whether the plug-in is active. When the knob is in the Off (counter-clockwise) position, all LED elements are unlit, plug-in processing is disabled, and UAD DSP usage is reduced (unless UAD-2 DSP LoadLock is enabled).

Link The Link switch is a software-only addition that allows the two sets of controls for each channel to be linked for ease of operation when both channels require the same values, or unlinked when dual-mono operation is desired. The Link parameter is stored within presets and can be accessed via automation.

Important: When unlink is switched to link, channel 1 controls are copied to channel 2. Control offsets between channels are lost in this case.

When set to Link (up position), modifying any channel one or channel two control causes its adjacent stereo counterpart control to snap to the same position (channel 1 & 2 controls are ganged together in Link mode).

When Link is active, automation data is written and read for channel one only. In this case, the automation data for channel one will control both channels.

Note: When Link is active, changing channel two parameters from a control surface or when in "controls only" (non-GUI) mode will have no effect.

When set to unlink (down position), the controls for channels one and two are completely independent. Unlink is generally used in mono mode. When unlinked, automation data is written and read by each channel separately.

Note: If disparate values are set under the unlinked state, the left channel will override the right channel when Link is activated.

Massive Passive Latency

The Massive Passive and Massive Passive Mastering EQs use an internal upsampling technique to facilitate their amazing sonic accuracy. This upsampling results in a slightly larger latency than other UAD plug-ins. See "Upsampled Plug-Ins" on page 563 for more information.

Note: Compensating for Massive Passive is not required if the host application supports full plug-in delay compensation throughout the signal path, or when it is used only on the outputs.

Notes from Manley Laboratories

- Do not assume the knob settings "mean" what you expect they should mean. Part of this is due to the interaction of the controls. Part is due to the new shelf slopes and part due to a lack of standards regarding shelf specification.
- You may find yourself leaning towards shelf frequencies closer to the mids than you are used to and the "action" seems closer to the edges of the spectrum than your other EQs. Same reasons as above.
- You may also find yourself getting away with what seems like massive amounts of boost. Where the knobs end up, may seem scary particularly for mastering. Keep in mind that, even at maximum boost, a wide bell might only max out at 6 dB of boost (less for the lowest band) and only reaches

20 dB at the narrowest bandwidth. On the other hand, because of how transparent this EQ is, you might actually be EQing more than you could with a different unit. Taste rules, test benches don't make hit records, believe your ears.

- Sometimes the shelves will sound pretty weird, especially (only) at the narrow bandwidth settings. They might seem to be having a complex effect and not only at the "dialed in" frequency. This is certainly possible. Try wider bandwidths at first.
- If you seem to be boosting all 4 bands at widely separated frequencies and not hearing much "EQ" as you might expect (except for level) this is a side-effect of a passive EQ and probably a good thing. To get drastic sounding EQ you should try boosting a few bands and cutting a few bands. In fact, it is usually best to start with cutting rather than boosting.
- A reasonable starting point for the Bandwidth for shelves is straight up or between 11:00 and 1:00. It was designed this way and is roughly where the maximum flatness around the "knee" is, combined with a well defined steep slope.
- The Massive Passive may sound remarkably different from other high end EQs and completely different from the console EQs. Yes, this is quite deliberate. Hopefully it sounds better, sweeter, more musical and it complements your console EQs. We saw little need for yet another variation of the standard parametric with only subtle sonic differences. We suggest using the Massive Passive before tape, for the bulk of the EQ tasks and then using the console EQs for some fine tweaking and where narrow Q touch-ups like notches are needed. The Massive Passive is equally at home doing big, powerful EQ tasks such as is sometimes required for tracking drums, bass and guitars, or for doing those demanding jobs where subtlety is required like vocals and mastering.

Additional Information

The original (and rather lengthy) user manual written by Manley Labs for the hardware unit contains a wealth of great information about the philosophy, design decisions, and use of the Massive Passive EQ. It is highly recommended reading for those interested in technical details. The manual can be found on their website, along with info about their other great products:

CHAPTER 24 Manley Stereo Variable Mu Limiter Compressor

Introduction

The Manley Stereo Variable Mu Limiter Compressor has been Manley Lab's flagship compressor since 1994. The Variable Mu's Class-A, tube and custom transformer-driven design epitomizes hand-made boutique craftsmanship. The Variable Mu is considered the gold standard among mix engineers thanks to its smooth, transparent dynamics control, and ability to add clarity and cohesion to stereo buses or an entire mix.

Developed under Manley Labs' rigorous scrutiny, the Manley Variable Mu Compressor plug-in is a thorough emulation of this legendary tube limiter, and is based on the coveted "6BA6 T-BAR Tube Mod" unit. Now, this modern classic is available exclusively for UAD-2 hardware and Apollo interfaces.

Now You Can:

- Add tube-enhanced glue, definition, and fidelity to individual tracks, stereo buses or an entire mix
- Inject subtle harmonic distortion with signature Manley tube coloration into your most important signal chains
- Link channels for a precise, perfectly matched stereo image, or unlink for individual channel control of gain and dynamics
- Select from Left/Right or Mid/Side operation for precise control of mono and stereo elements
- Use the plug-in-only Dry/Wet Mix control to easily dial-in parallel compression

Variable Mu Screenshot

Figure 74. The Manley Stereo Variable Mu plug-in window

Variable Mu Overview

The Manley Stereo Variable Mu Limiter Compressor is a highly flexible two-channel processor for adding transparent dynamics control and tube warmth to mix and master buses or individual tracks.

While the Manley Variable Mu uses the remote cut-off style gain reduction found in the Fairchild and other classic limiters, it has a sound and character all its own. Incorporating a traditional dual-triode gain reduction design which is constantly re-biased by the sidechain control voltages, the Variable Mu combines Manley's hand-selected tubes and in-house transformer manufacturing to create a unique variable gain compressor design with stunning transparency. This lets you treat source material with velvety-smooth gain reduction, while infusing warm harmonic content, free of audible compression artifacts.

The Manley Variable Mu can operate in stereo or as a dual-mono device.

Dual Mono/Stereo Processing

Dual Mono

When set to Left-Right (versus Mid-Side) and the sidechain is unlinked, the processor operates as a dual mono device. Except for the ganged Dual Input control, the left and right channels are completely independent, and each channel can have unique settings.

Stereo

When set to Left-Right and the sidechain is linked, the plug-in is operating as a stereo device. The left signal is fed to the left channel compressor, and the right signal is fed to the right channel compressor. The two compressors are constrained so that they both compress the same amount at any instant, preventing transients that appear only on one channel from shifting the stereo image of the output (any big transient on either channel will cause both channels to compress). The amount of compression will be similar to the amount of compression for a transient which appears on both channels at the same time.

In stereo operation, the controls for the left and right channels can be unlinked so they are independent and can be adjusted separately. Threshold, attack, and recovery can be set independently to cause the compressor to be more sensitive to instruments which are panned to one side or the other. Output controls can be set separately in order to correct an overall image shift at the output.

Mid-Side
ProcessingThe Manley Variable Mu can perform dynamics processing on the middle
and side components of stereo signals independently. In other words, the
monophonic (middle, or sum) and/or stereo (side, or difference) components
of a stereo source signal can be processed separately from the other compo-
nent.

Mid-Side processing is accomplished by first routing the stereo source signal through a sum/difference matrix on input which separates a stereo source signal into its mono and stereo signal components. The mid-side components are then compressed or limited independently. Finally, the mid-side components are recombined into a normal stereo signal via another sum/difference matrix on output.

In the Variable Mu, the left+right (sum) middle signals are routed to the left channel, and the left-right (difference) side signals are routed to the right channel. The two channels can work independently of each other, or the dynamics sidechain control signal can be optionally linked for creative uses.

The Variable Mu has separate Mid-Side switches for input and output. The M-S IN switch activates the sum/difference matrix on input (encode) and the M-S OUT switch activates the sum/difference matrix on output (decode). The separate matrices allow for using only "half" of a full encode/decode circuit

UAD Powered Plug-Ins Manual

on input or output (but not both) when a full encode/decode process is not desired. For example, this feature can be used to decode stereo tracks recorded with the mid-side microphone technique back into a standard left/right stereo signal.

Note: Each sum/difference matrix simply inverts the stereo signal type from left-right to mid-side, or from mid-side to left-right. They don't distinguish between the original signal type, so they can be used to convert either type to the other type.

- Variable MuThere are two independent processors within the Variable Mu. Depending on
the state of the two Left-Right/Mid-Side switches (one for input and one for out-
put) and the Sidechain Link switch, numerous operating modes are possible.
- **Modes Table** The switch positions required for various operating modes are shown in the table below, followed by descriptions of the modes.

Table 22. Variable Mu Modes

Input Matrix	Output Matrix	Sidechain Link	Operating Mode
L-R	L-R	Unlinked	Dual Mono
L-R	L-R	Linked	Stereo Left/Right
M-S	M-S	Unlinked	Stereo Mid/Side (encode+decode)
M-S	L-R	Unlinked	Stereo Mid/Side (input matrix only)
L-R	M-S	Unlinked	Stereo Mid/Side (output matrix only)

Mode Descriptions

Dual Mono

In dual mono mode, the Variable Mu operates as two separate monophonic dynamic processors with independent control of the left and right channel signals. There is no interaction between the two processors.

Stereo Left/Right

In this mode, the Variable Mu operates as a typical stereo dynamics processor. The dynamics control signal sidechain of the two compressors are linked so that they both compress the same amount at any instant, preventing transients which appear on only one channel from shifting the stereo imaging of the output.

Dual Mid/Side (encode+decode)

In this mode the Variable Mu operates as two monophonic processors with independent control of the middle and side components of the two input signals. The input signals are encoded by the mid/side (sum/difference) matrix before processing and there is no interaction between the two processors. The left channel processes the mid component, the right channel processes the side component, and the mid/side components are decoded back into a normal stereo signal at the outputs.

Dual Mid/Side (input matrix only)

This mode is the same as Dual Mid/Side, except the signal components are not routed through the output matrix.

Dual Mid/Side (output matrix only)

This mode is the same as Dual Mid/Side, except the signal components are not routed through the input matrix.

Operating Headroom The Headroom control, which is a UAD-only feature not found in the original hardware, enables adjustment of the internal operating reference level for the Manley Variable Mu. Headroom enables best practice operating level matching, or it can be used creatively to expand the sonic range of the processor. By fine-tuning Headroom, the non-linear I/O distortion and compression response characteristics can be tailored independently of signal input levels.

> By increasing the Headroom (by rotating the control counter-clockwise), signals at the input can be pushed higher before they compress. For complete details about this feature, see "Headroom" on page 248.

Unmarked Controls Some continuous controls (Dual Input, Threshold, Attack, Output) have a range of zero to ten when viewed in controls mode (if supported by the DAW). As with the original hardware, these controls are not marked with absolute values and are designed to be set "by ear" instead of by selecting pre-defined values. Artist Presets The Manley Variable Mu includes artist presets from prominent Variable Mu users. The artist presets are in the internal factory bank and are accessed via the DAW application's preset menu. The artist presets are also copied to disk by the UAD installer so they can be used within Apollo's Console application. The presets can be loaded using the Settings menu in the UAD Toolbar (see "Using UAD Powered Plug-Ins" in Chapter 7 of the UAD System Manual).

Manley Variable
Mu LatencyThe Manley Variable Mu plug-in uses an internal upsampling technique to
achieve sonic design goals. The upsampling results in a slightly larger latency
than most other UAD plug-ins (between 55 and 88 samples, depending on
the sample rate).

These additional samples are automatically compensated by modern host DAWs. See "Upsampled Plug-Ins" on page 563 for more information.

Manley Variable Mu Controls

Dual Input This continuously variable control determines the signal input level (gain) for both channels of the processor. Higher levels result in a more colored signal. Lower levels result in a more transparent or natural sound.

Threshold

This continuously variable control determines the amount of compression to be applied to the channel. Rotate Threshold towards MIN (counter-clockwise) to lower the threshold and increase compression.

Tip: Signals below the threshold are not compressed.

Input Gain versus Threshold

The amount of signal compression is determined by both the Dual Input and Threshold controls. If one is increased and the other decreased, the compression characteristics won't change much, but the color characteristics will.

Tip: For less color with the same amount of compression, lower the input gain and lower the threshold control.

Attack sets the amount of time that must elapse once the input signal reaches the Threshold level before compression is applied. The faster the Attack, the more rapidly compression is applied to signals above the threshold.

The Attack range is continuously variable from 70 milliseconds (when set to SLOW) to 25 milliseconds (when set to FAST).

Recovery

Attack

The Recovery (release) knob sets the time it takes for processing to cease once the input signal drops below the threshold level. The available values are shown in the table below. The default setting is Medium Fast.

Table 23. Recovery Knob Values

Knob Value	Time (seconds)
Slow	8
Medium Slow	4
Medium	0.6
Medium Fast	0.4
Fast	0.2

Output

Output provides continuous attenuation of the Variable Mu's signal level at the output of the plug-in. Note that output adjustment is only possible when the In/Bypass switch is set to In.

Note: This control has no effect on the dry signal component.

Compress/Limit

The Compress/Limit switch sets the channel to function as a limiter or a compressor.

Tip: For limiting or compression to occur, signal levels must exceed the Threshold value.

Limit

When set to Limit, the ratio starts at 4:1 and moves up to 20:1 when limiting exceeds 12 dB. The limiter provides a sharper knee to catch peaks, but actually softens as more limiting is used.

Compress

When set to Compress, the ratio is set to 1.5:1 with a soft-knee characteristic. Soft-knee provides a more subtle compression resulting in a natural, less compressed sound.

Note: As with the original hardware, the Variable Mu plug-in can never achieve greater than –10 dB of gain reduction.

Sidechain Filter When set to HP SC, this switch rolls off low frequencies in the dynamics control sidechain. The signal is attenuated by -3 dB at 100 Hz with a slope of 6 dB per octave. When set to FLAT, the sidechain is unfiltered. The default setting is FLAT.

HP SC

Removing low-frequency content from the sidechain by engaging the filter can reduce excessive gain reduction and/or "pumping" on bass-heavy audio signals without reducing bass content of the audio signal itself.

Bypass

BYPASS

The Bypass switch determines whether or not the incoming signal is processed by the plug-in. When set to Bypass, the source signal is unaffected.

Mid-Side/
Left-RightNote: For an overview of this feature, see "Mid-Side Processing" on
page 241.

These two switches enable the sum/difference matrix for the input and/or the output. The switch on the left (labeled IN) enables the processor input matrix, and the switch on the right (labeled OUT) enables the processor output matrix.

- For mid/side compression on a standard stereo left-right signal, set both IN and OUT switches to M-S.
- For single-ended processing (for example, to process a stereo track recorded with a mid/side microphone technique), set only one switch to M-S.
- Sidechain Link should generally be disabled for traditional mid-side processing. Of course, the sidechains can be linked for creative purposes.

IN

When the M-S switch labeled IN is set to L-R, incoming stereo signals are passed directly into the compressor inputs, bypassing the input sum/difference matrix.

246

When set to M-S, incoming stereo signals are passed through the sum/difference matrix, converting one signal type (left/right or mid/side) to the other type before compression.

OUT

When the M-S switch labeled OUT is set to L-R, outgoing (post-compression) stereo signals are passed directly to the outputs, bypassing the output sum/difference matrix.

When set to M-S, outgoing stereo signals are passed through the sum/difference matrix after compression, converting one signal type (left/right or mid/side) to the other type before being output.

When this control is set to Link, it causes the two channels of the com-LINK pressor to compress in equal amounts. This does not mean that the SIDECHAIN compressor will be equally sensitive to either channel however; that depends on the settings of the other controls.

When Sidechain is set to LINK but Controls Link is off, the Threshold controls can be set independently to cause the compressor to be more sensitive to instruments which are panned to one side or the other. Output controls can be set separately in order to correct an overall image shift at the output.

Controls Link This switch links the controls for the left and right channels of the processor. When set to LINK, adjusting the left channel controls will force the equivalent right channel controls to move to the same position.

To read and write automation data for both channels independently when in dual-mono mode, Controls Link must be disabled.

Important: When unlink is switched to link, the left channel values are copied to the right channel, and any control offsets between channels are lost.

Mix

Sidechain Link

The output balance between the signal processed by the plug-in and the original dry source signal can be adjusted with the Mix control. Mix facilitates parallel compression techniques without having to create additional routings in the DAW.

When set to DRY, only the unprocessed source signal is output. When set to WET (the default value), only the processed signal is output. When set to the center position (50%), an equal blend of both the dry and wet signals is output. The balance is continuously variable throughout the control range.

Note that the dry signal is unaffected by the Variable Mu's Output control.

Tip: Click the "MIX" text label to set the control to the 50% position. Click the "DRY" text label to set the control to the minimum position. Click the "WET" text label to set the control to the maximum position.

Headroom The Headroom control is provided to allow best practice operating levels and accommodate applications where high amounts of gain reduction are not desired. Headroom simply changes the internal operating level so that the plug-in is not "pushed" into gain reduction as much.

Note: There is only one headroom parameter. Although the Headroom control appears twice in the Variable Mu window, they are permanently linked.

Headroom can be set (in dB) to 4, 8, 12, 14, 16, 18, 20, 24, or 28. The default value is 16 dB (when the set screw "dot" is in the straight up 12 o'clock position). Note that Headroom is *increased* as the dB value *decreases*.

Tip: Click the "HEADROOM" text label to return the control to the default value.

At higher dB values (clockwise rotation), signals will push the plug-in into gain reduction (and more non-linearity and "good" harmonic distortion color) more easily. Set the control to a lower value (counter-clockwise rotation) when less gain reduction and less color is desired.

Note: To avoid the temporary gain increases that can result when adjusting Headroom, automating this control is not recommended.

Keep in mind there are no hard and fast headroom rules. Feel free to experiment with the various positions of the Headroom control regardless of the audio source. If it sounds good, use it!

On/Off

This switch determines whether the plug-in is active. When set to OFF CO ON the Off position, the VU meters go dark to indicate signal processing has ceased. In this state, plug-in processing is disabled and UAD DSP usage is reduced (unless UAD-2 DSP LoadLock is enabled)

Gain Reduction Meters

Dual VU meters display the amount of gain reduction in decibels. In typical use, adjusting Threshold towards MIN (counter-clockwise) results in the VU meters displaying higher amounts of reduction.

Additional Information

The original user manual written by Manley Labs for the hardware unit contains a wealth of great information about the philosophy, design decisions, and use of the Massive Variable Mu. It is highly recommended reading for those interested in technical details. The manual can be found on their website, along with info about their other great products:

CHAPTER 25 Moog Multimode Filter

Overview

If UA were able to conceive a product with Moog, what would it be? The answer is revealed in the new UAD Moog Multimode Filter, which delivers the first truly analog-sounding VCF (voltage controlled filter) emulation made for mixing, performing, creating, or destroying. The Moog Multimode Filter is a 'digital-only' tabletop filter set that combines the best of Bob Moog's classic designs with select features from his final Voyager instrument. UA modeled the analog behavior of the historical 4-pole ladder filter conceived by the world's most recognizable electronic instrument maker right down to the self-oscillation, saturation and non-linearities of its analog counterpart. As the name suggests, the heart of the Moog Multimode Filter is the switchable Lowpass, Highpass and Bandpass filter that allows Moog's signature self-oscillation and extreme resonance in any of the three modes, bringing a new level of sophistication to Moog filter designs of the past.

The UAD Moog Filter algorithm uses a special filter structure that was created especially to eliminate "digital" artifacts for time-varying filters. An expensive DSP technique was used to calculate the response of the nonlinear feedback loop surrounding the saturation and filter elements.

Warning: Like most resonant filters, UAD Moog Filter has the potential to create unpredictable sonic results that can result in unexpected jumps in output amplitude. Depending on the source material, input levels, and parameter values, the filter output can suddenly get extremely loud, with the potential to damage speakers and/or hearing. This condition is particularly susceptible when the simultaneous conditions of high gain, low filter cutoff, and high resonance values are applied, and/or when the LFO sweeps into these conditions. Use caution and/or low monitoring levels when dialing in extreme parameter values to avoid speaker and/or hearing damage!

Moog Filter Screenshot

Figure 75. The UAD Moog Filter plug-in window

Moog Filter Controls

The Moog Filter is true stereo, with separate filters for the left and right channels. The dual filters share the same controls. The only time the left and right filters diverge is when Filter Spacing or LFO Offset are not zero.

Drive

Drive controls the amount of saturation gain before the filter. Drive is where much of the sonic "juice" in the UAD Moog Filter originates. Drive can change the signal from clean to slightly overdriven to extremely distorted, particularly when used in conjunction with the Boost switch (see "Boost" on page 256).

Gain (SE only)

The non-linear modeling of Drive characteristics is extremely DSP-intensive. For this reason, Drive is not available on the SE version of UAD Moog Filter. In UAD Moog Filter SE, the parameter is named Gain instead of Drive, and is a straight (non-modeled) input gain control.

The range of Drive/Gain is 0 to +40 dB of gain. Drive/Gain affects both the wet and dry signals (the control is heard when Mix is zero and/or when Bypass is engaged). This gain range closely mimics the external input section of the Minimoog.

Warning: Due to these differences in input structure, cut and pasting of full-to-SE and SE-to-full presets may cause noticeable differences in gain. Keep hold of the master fader!

 Drive/Gain LED
 The Drive/Gain multicolor LED indicates the plug-in signal level just after the Drive/Gain control. The Drive/Gain LED operates when the plug-in is in Bypass mode, but not when Power is off.

 The Envelope controls (Envelope level)
 The Envelope controls (Envelope level)

GAIN

Envelope The Envelope controls (Envelope knob, Smooth/Fast switch) closely mimic the controls of the MF-101 Moogerfooger. However, UA has broadened the sonic palette with a negative range allowing unique negative envelope effects.

The cutoff frequency of UAD Moog Filter can be modulated by the amplitude of the signal coming into the plug-in. This function is typically called an "envelope follower" or "auto wah" because the cutoff frequency "follows" the signal input level. The amount and speed of the envelope response can be adjusted.

The envelope knob determines how much the filter cutoff frequency is affected by the signal input level. Positive and negative values are possible. Positive values increase the filter cutoff as the input amplitude increases (the filter opens as the signal gets louder). Negative values decrease the filter cutoff as input amplitude increases (the filter closes as the signal gets louder).

The greater the value (either positive or negative), the greater the amount of filter modulation (the cutoff frequency range is increased with greater values).

Tip: Click the knob label ("ENVELOPE") to return the value to zero.

Envelope LED

ENVELOPE This enve

This LED indicates the relative peaks of the control envelope. The envelope LED does not illuminate when the plug-in is in Bypass mode or when Power is off.

Smooth/FastThis toggle switch determines the release time of the control envelope. In
Smooth mode, the release time is 200 milliseconds. In Fast mode, the release
time is 40 milliseconds. In both modes, the attack time is 25 milliseconds.

In typical applications, Fast mode is useful on percussive sounds, while Smooth mode is better suited to sounds with longer and/or uneven decays.
This parameter defines the cutoff frequency of both filter channels in all modes (lowpass, bandpass, highpass). UA has expanded the available frequency range of 20 Hz to 12 kHz on the MF-101 Moogerfooger to the broader available range of 12 Hz to 12 kHz on the Moog Mulitmode Filter.
In lowpass mode, frequencies above the cutoff are attenuated. In highpass mode, frequencies below the cutoff are attenuated. In bandpass mode, the cutoff value is the center frequency; attenuation occurs above and below the cutoff value in this mode.
Tip: The cutoff value can be adjusted in musical semitone (1/2 step) incre- ments/decrements using coarse control shortcuts, and 1/4 semitone incre- ment/decrement using fine control shortcuts. See "Shortcuts" in Chapter 7 of the UAD System Manual for details.
Resonance determines the amount of filter feedback, which accentuates the harmonic content at the cutoff frequency. Higher values can produce a "whis- tling" quality to the filter, and at very high values the filter may self-oscillate.
Resonance works the same way in all three filter modes.
The filter slope is determined by this switch. The slope defines how "steep" the frequencies above the cutoff in lowpass mode (or below the cutoff in highpass mode) are rolled off.
2-Pole
In 2-pole mode, the filter has a slope of 12 dB per octave. For example, in lowpass mode frequencies that are double the cutoff frequency (an octave) are attenuated by 12 dB. 2-pole filtering is less aggressive than 4-pole mode, but has its own unique sound that you may find is better suited for certain types of signals.

4-Pole

4-Pole mode has a steeper slope (24 dB per octave), so the filtering is more obvious. This is the "classic" (and luscious) Moog filter, in all its glory, that has been employed on just about every Moog product, from the Modular to the Minimoog to the Voyager.

Step/Track This switch is a smoothing control for the filter cutoff frequency parameter. Smoothing is most obvious on continuous filter sweeps when varying the cutoff rapidly with the knob or automation. Step mode can be desirable when sudden cutoff changes are automated and other creative purposes.

Smoothing is on in the Track position, and off in the Step position.

Note: When set to Track, the plug-in does not "track" the input signal frequency like a synthesizer filter.

Mode This control is the heart of the Moog Multimode filter, combining Moog's classic lowpass filter with highpass and bandpass in one control. Unlike Moog highpass and bandpass filters of the past, UA's design presents Moog's signature self-oscillation in all three modes, bringing a new level of sophistication to Moog filter designs of the past. The knob switches between the available filter types.

Lowpass

Frequencies above the cutoff value are filtered.

Bandpass

Frequencies above and below the cutoff value are filtered.

Highpass

Frequencies below the cutoff value are filtered.

Spacing Spacing inversely offsets the filter cutoff values for the left and right channels. In other words, positive Spacing values increase the right channel cutoff while lowering the left channel cutoff, and vice versa.

Spacing is borrowed from Bob Moog's Voyager instrument, and separates the hard-panned filters by up to three octaves. Unlike the original however, both filters are moving away from each other in pitch, rather than one fixed filter plus one adjustable filter pitch. Positive or negative values enable positioning the de-tuned filters from left to right, low to high, or high to low.

Spacing can create great stereo spacial effects. When the filter is in Mono mode, both filters are still heard.

Tip: Click the knob label ("SPACING") to return the value to zero.

LFO	The LFO (low frequency oscillator) modulates the filter cutoff frequency. Sev- eral waveform shapes are available. The LFO can be synchronized to the tempo of the host (see Free/Sync below).
Amount	Amount controls the depth of the LFO filter cutoff modulation. A higher value will have a broader filter sweep.
Rate	Rate controls the speed of the LFO. The available range is from 0.03 Hz to 25 Hz in Free mode, or 16/1 to 1/64 to in Sync mode.
Rate LED	The LFO Rate LED illuminates in conjunction with the LFO rate, once per LFO cycle. Clicking this LED resets the LFO cycle (see "LFO Reset" below).
LFO Reset	The LFO is reset to its zero crossing by clicking the LFO Rate LED. This parameter can be automated for mixing or bouncing.
	Normally the LFO is "free running" but this behavior is not always desirable. For example, if you are using LFO filter modulation, you may want playback to always sound exactly the same when bouncing or mixing. To accomplish this, the LFO must be started at the same place (zero crossing) of the LFO waveform. Reset enables this sonic consistency when using the LFO.
Free/Sync	This switch defines whether the LFO is synchronized to the tempo of the host application (if this feature is supported by the host). See Chapter 8 "Tempo Sync" in the UAD System Manual for more information.
	To ensure the LFO phase is consistent when in Sync mode, automate the Reset parameter (see "LFO Reset" on page 255).
Value	The Value display depends upon the setting of the Free/Sync switch. Value displays the LFO frequency in Free mode, and the tempo sync note value in Sync mode. See Chapter 8 "Tempo Sync" in the UAD System Manual for more information.
Wave	This control determines the waveform shape used by the LFO. Six waveshapes are available: Sine, Triangle, Sawtooth-Up, Sawtooth-Down, Square, and Random.

Offset	Offset adjusts the polarity between LFO signals for the left and right channels. The available range is ±180 degrees.
	Offset can create great stereo spacial effects. When the filter is in Mono mode, both filters are still heard.
	Tip: Click the knob label ("OFFSET") to return the value to zero.
Mix	Mix varies the amount of filtering that is occurring. It is not a true dry/wet con- trol; it mimics the mix function on the MF-101 Moogerfooger. When Mix is at zero, the Drive/Gain control (and Boost on non-SE version) are still active and audible.
	Setting Mix at zero is the same as setting the Effect/Bypass switch to Bypass.
Stereo/Mono	The left and right channel filters are always independent in the UAD Moog Fil- ter. However, when this switch is set to Mono, the left and right output chan- nels are summed. In Stereo mode, the left/right separation is retained.
Output	The Output control changes the gain at the output of the plug-in. The available range is ±20 dB.
Output LED	This LED gives a visual indication of the plug-in output level. The Output LED is active when Bypass is enabled, but not when Power is off. When the LED is red, the output is 0 dBfs.
Effect/Bypass	When Bypass is enabled, filter processing is inactive. Drive/Gain and Output still operate in Bypass mode. Enabling Bypass has the same effect as setting Mix to zero.
	If the Free/Sync switch is set to Free, the LFO phase is reset to zero when Bypass is switched to Effect.
Boost	Boost shifts the "Drive" gain range up a full 20 dB, while simultaneously shift- ing the Output range down –20 dB. This mimics the behavior of the external input on the Minimoog.
	Note: This control is not available on the SE version.
Power	Power disables the plug-in altogether and disables DSP processing. When off, the background will "dim" much in the same way the Voyager's panel does when powered off.

Moog Filter SE

Overview The UAD Moog Filter SE is derived from the UAD Moog Filter. Its algorithm has been revised (primarily the elimination of the Drive circuit) in order to provide sonic characteristics very similar to the Moog Filter but with significantly less DSP usage. It is provided to allow Moog Filter benefits when DSP resources are limited. The UAD Moog Filter SE sounds great even without Drive, and is very usable in many situations.

The Moog Filter SE interface can be differentiated from the full Moog Filter by color and the module name. The Moog Filter SE is uses the "Luna" background and maple sides borrowed from the Voyager "Select Series." The full version uses the Voyager's "electric blue" backlighting and mahogany sides."

Figure 76. The UAD Moog Filter SE plug-in window

Moog Filter SE Controls The Moog Filter SE controls are nearly the same as the Moog Filter. The exceptions are the Drive related controls ("Drive" and "Boost") are unavailable on the SE model, and the "Drive" control is replaced with a straight (non-modeled) "Gain" control.

Please refer to the Moog Filter section for Moog Filter SE control descriptions (see "Moog Filter Controls" on page 251).

Note: When preset settings are copied from the full Moog Filter version to the SE version, the Boost (+20) switch value is retained, even though the parameter is not available for SE. If you subsequently copy from SE back to the full version, the original Boost value is pasted.

Moog Filter Latency

The Moog Filter (but not the Moog Filter SE) uses an internal upsampling technique to facilitate its amazing sonic quality. This upsampling results in a slightly larger latency than other UAD plug-ins. See "Upsampled Plug-Ins" on page 563 for more information.

The Moog Filter SE does not require additional latency compensation because it is not upsampled.

Note: Compensating for Moog Filter is not required if the host application supports full plug-in delay compensation throughout the signal path, or when it is used only on the outputs.

CHAPTER 26

MXR Flanger/Doubler

Classic Electronic Flanging

For more than 30 years, musicians and engineers have relied upon the MXR Flanger/Doubler as one of best-sounding bucket-brigade flanging effects ever made. Through its signature flanging, doubling, and delay effects, the MXR Flanger/Doubler imprints a unique stamp on guitars, bass, keys, drums, or just about any source needing movement and depth. Developed in close collaboration with Dunlop Manufacturing, the MXR Flanger/Doubler plug-in for the UAD-2 platform replicates the legendary sound of this classic studio and stage effect with unparalleled accuracy.

The MXR Flanger/Doubler plug-in for UAD-2 is perfect for adding that "special something" to your tracks, and getting the creative juices and sound-shaping possibilities flowing. This plug-in models the original hardware unit in meticulous detail, and makes all its chewy analog goodness available for the first time in plug-in form. From guitars and basses to drum breaks, the MXR Flanger/Doubler plug-in will get your tracks moving.

- **History** Flanging originated as a tape effect where two tape machines are playing two identical and synchronized signals, and one is gradually delayed to create unique comb filtering effects. In the late 70's, MXR introduced the famed Flanger/Doubler unit which, unlike tape flanging, recreated this effect electronically via "bucket brigade" design.
- **Bucket-Brigade** Technology A bucket-brigade device ("BBD") is an analog circuit that produces a delay by storing the signal in a series of capacitors, passing the stored signal from one capacitor to the next with each clock cycle. Because the signal is degraded with each pass, audio delay lines using BBDs tend to significantly color the signal.

The name is derived from human bucket brigades, whereby a line of many people remain stationary while passing many buckets from one person to the next. Bucket brigades were commonly used by firefighters to deliver water to a fire more efficiently than would be possible if each person were to carry a single bucket from the water source to the destination.

MXR Flanger/Doubler Screenshot

Figure 77. The UAD MXR Flanger/Doubler plug-in window

Operational Overview

Model 126 The MXR "Model 126" Flanger/Doubler is an analog delay processor that uses "bucket-brigade" technology to create short signal delays. The delay time can be modulated manually, or automatically with a low frequency oscillator (LFO). The delayed signal can be mixed with itself in a feedback loop ("regenerated"), and its polarity can be inverted. The amount of processed signal relative to the original signal is adjustable.

> All sonics and control behaviors are authentically modeled, including the inherent aliasing characteristics and dry signal path coloration.

Modes Flanger

The flanging effect in MXR Flanger/Doubler is generated by using very short delay times whereby the delayed (wet) signal is not heard as separate from the original (dry) signal. When this delayed signal is combined with the dry signal, the comb filtering that is the essence of the flanging effect is generated. By modulating ("sweeping") the delay time, the response of the comb filtering is modified, and the characteristic "swoosh" is produced. Additional sonic options are possible by increasing the delayed signal feedback ("regeneration") to produce a deeper and more resonant effect, and/or reversing the polarity ("invert") to give the sound a more "hollow" character.

Doubler

When in Doubler mode, all controls have the exact same functionality as Flanger mode; the only difference is that the available delay times are longer in this mode. The delayed signal produces a very short echo, hence a "double" of the original signal is heard.

- Software-Only Features The UAD MXR Flanger/Doubler plug-in has some features not included in the original hardware. The LFO rate can be synchronized to the tempo of the DAW session; the LFO can be reset; Stereo mode can apply processing to both sides of a stereo signal; and stereo output can be summed to mono.
- **Stereo Functionality** The original hardware is monophonic. To accommodate modern applications, the plug-in can be used in mono-in/stereo-out and stereo-in/stereo-out configurations. Two different stereo modes are available, and the stereo output can be summed to mono if desired. See "Stereo Mode" on page 262 for details.
- In Use The MXR Flanger/Doubler is well suited for sound-shaping, recording, and mixing, and even for adding some post-production flavor. Flanging is particularly popular as an individual effect on a wide range of musical sources including guitar, bass, drums, keyboards, full source material, and more. Another common use for the MXR Flanger/Doubler is as a group effect, where effecting more than one signal is desired. Try applying the MXR Flanger/Doubler to drum busses or even the entire mix, most often for a brief period in the song, such as a break or bridge. In addition to Flanging, the Flanger/Doubler excels as a short-range delay/doubler.

MXR Flanger/Doubler Controls

Buttons	The buttons on MXR Flanger/Doubler are two-state switches. The buttons are ON when they are in the "DOWN" position. When ON/DOWN, they are gray with a darker "shadow." When OFF/UP, they are white.	
Power	Power is the plug-in bypass control. Power is ON when the LED is red. When set to OFF, emulation processing is disabled, the LEDs are dimmed, and DSP usage is reduced (if DSP LoadLock is inactive).	
	Power is useful for comparing the processed settings to the original signal.	
Effect	FLANGER This button switches between Flanger and Doubler modes. It defines the range of signal delay available for the mode. The function of all the other controls is the same in both modes.	
	See "Modes" on page 260 for additional details about the two effects.	

Flanger

When in the "down" (gray) position, Flanger mode is active. This is the default setting.

Doubler

Doubler mode is active when the button is in the "up" (white) position.

Stereo Mode This software-only switch modifies the processed signals at the outputs when used in a stereo-output configuration.

The control does not switch the processor between mono and stereo modes; both modes are true stereo (when configured for stereo output).

In both stereo modes (Single and Dual), stereo separation of the dry signals is maintained, and the stereo signal is not mixed to mono before processing is applied.

Note: This function is only available when the plug-in is used in a mono-in/stereo-out or stereo-in/stereo-out configuration. When used in a mono-in/mono-out configuration, the switch has no effect.

Single

When in the "up" (white) position, Single mode is active. This is the default setting.

In Single mode, the left and right signals are processed identically and the Sweep LFO for both channels are in phase.

Dual

When in the "down" (gray) position, Dual mode is active.

When Dual mode is enabled in a stereo-out configuration, the processing is applied to both the left and right channels. In this mode, the settings are the same for both processors, but a phase difference of 180° (antiphase) is applied between the Sweep LFO of the two channels. When Sweep Width is above 0% in Dual mode, this phase offset produces a swirling effect that pans back-and-forth.

Manual

This continuous control determines the delay time of the processor. The delay time is modulated by the Sweep LFO when the Width value is higher than 0%.

The available range of the control depends on the setting of the Effect button. In Flanger mode, the available delay time range is 4.9 milliseconds to 0.33 milliseconds. In Doubler mode, the available delay time range is 66 milliseconds to 18.5 milliseconds.

Sweep

The Sweep parameters (Width and Speed) control the LFO (Low Frequency Oscillator) that modulates the delay time of the processor.

Width

Sweep Width controls the amount of modulation applied to the delay time LFO. The available range is 0 – 100%.

At 0%, no modulation occurs and delay time is determined by the Manual setting. As Width is increased, the amount of modulation becomes "wider" (a broader sweep). At 100%, the delay time sweeps throughout its entire range, automatically creating the same sound as moving the Manual control repeatedly back and forth from minimum to maximum.

Speed

Sweep Speed controls the rate of modulation applied to the delay time LFO. The available range is 0.02 Hz to 15.96 Hz (this is the actual range of the original hardware; the knob text on the hardware panel doesn't match exactly). The current speed is indicated by the Sweep LEDs and also shown in the Rate Display.

The Sweep Speed can be synchronized to the tempo of the host application by engaging the Sync function.

M	IX
0	
DRY	DELAY

This continuous control adjusts the blend between the original dry signal and the processed wet signal(s). The available range is 0 - 100%.

When set to minimum, only the dry signal is heard. When set to maximum, the signal is almost entirely wet, however a small amount of dry signal is present (like the original hardware).

When Mix is set to the minimum/dry position, the input signal is colored by the electronics of the unit (like the original hardware).

Regeneration This is a feedback control for the delay processor. The available range is 0 – 100%.

When set above its minimum value, the output of the effect is routed back to its input. As the value increases, a more resonant signal is produced. Regeneration has a governor that prevents feedback "runaway" (overload) even when set to the maximum value of 100%.

Mono

This switch sums the stereo output of the dry and wet signals to mono when the plug-in used in a stereo-output configuration. This function is useful for creative purposes or checking phase relationships. The output is stereo when the switch is in the "up" (white) position, and mono when the switch in the "down" (gray) position.

Mono is only available when the plug-in is used in a mono-in/stereo-out or stereo-in/stereo-out configuration. When used in a mono-in/mono-out configuration, the switch is locked in the Mono position.

Note: See "Stereo Mode" on page 262 for additional details about stereo output.

Invert This switch inverts the polarity ("phase") of the processed signal. The wet signal polarity is normal when in the "up" (white) position, and inverted when in the "down" (gray) position.

When the processed signal is inverted and combined with the dry signal, the resultant comb filtering has a different timbre than when polarity is normal. This is particularly evident in Flanger mode, which often sounds more "hol-low" when polarity is inverted.

Sync

The speed of the Sweep LFO can be synchronized to the tempo of the host application by engaging the Sync button. Tempo Sync is engaged when the button is in the "down" (gray) position and the LED above the button is illuminated.

See Chapter 8 "Tempo Sync" in the UAD System Manual for complete details about this feature.

Rate Display The rate of the Sweep LFO is displayed here. When Sync is inactive, the LFO speed is displayed in Hertz. When Sync is active, the LFO speed is shown as a beat division (or multiplier). The Rate Display is unique to the plug-in; the original hardware does not have this feature.

Sweep LEDs

The Sweep LEDs, located above the Manual knob, perform two functions: LFO rate indication and LFO reset.

Rate

The Sweep LEDs illuminate in tandem with the current Sweep Speed, providing a visual indication of the LFO rate. The Width amount must be higher than 0% for the LEDs to blink. As Width increases, the blinking is more obvious.

The manner in which the LED response manifests depends on the state of the Manual, Width, and Speed controls; their quirky behavior is the same as the original hardware.

Reset

The LEDs provide a mechanism to reset the Sweep LFO so the sweep cycle can be consistently controlled. The LFO cycle is reset to begin sweeping "downwards" in pitch (negative sweep) by clicking either LED. This function, which is not available on the hardware unit, can be automated for mixing or bouncing.

Normally the Sweep LFO is "free running" but this behavior is not always desirable. For example, you may want playback to always sound exactly the same when bouncing or mixing. To accomplish this sonic consistency, the Sweep LFO must be started at a specific place in the LFO cycle by using the Reset function.

MXR Flanger/Doubler Latency

This plug-in uses an internal upsampling technique. The upsampling results in a slightly larger latency than most other UAD plug-ins. See "Upsampled Plug-Ins" on page 563 for more information.

Note: Compensating for additional latency is not required if the host application supports full plug-in delay compensation throughout the signal path, or when it is used only on the outputs.

The MXR Model 126 Flanger/Doubler hardware unit

CHAPTER 27

Neve 1073 Preamp & EQ Collection

The Most Coveted Preamp and Equalizer Ever Made

The Neve 1073 console channel module is considered the most revered preamp and EQ circuit ever designed, and is certainly the most cloned and copied; Rupert Neve's 1073 easily tops the shortlist of all-time greatest audio production masterpieces. This Class-A, transistor mic/line amp with EQ epitomizes the "Neve essence," endearing it to engineers and producers worldwide.

Introduced in 1970, the 1073 was found in Neve consoles such as the Wessex A88 and 8014, and has been used on a massive number of popular recordings from the late-20th-century until today. Provide the same unmistakable clarity, sheen, and bite to your music that is nearly unattainable with any other unit, with the Neve 1073 Preamp and EQ Collection for UAD-2 and Apollo interfaces.

The only end-to-end Neve 1073 Circuit Emulation

The Neve 1073 for Apollo and UAD-2 provides all the features, unique circuit behaviors, and coveted sound of Neve's original hardware design. Modeling the dual-stage "Red Knob" preamp, revered three-band EQ, and post-fader output amplifier with obsessive detail and thoroughness, Universal Audio's Neve 1073 plug-in replicates the experience of its hardware inspiration with suspension-of-disbelief analog detail and precision. Start from the clear and punchy "more real than real" 1073 response. Turn it to a warming, class-A euphonic saturation. Push the circuit even further for audible–but never brittle–dynamically complex, harmonically rich Neve transistor clipping.

Figure 78. The Neve 1073 plug-in window

Figure 79. The Neve 1073 Legacy plug-in window

Figure 80. The Neve 1073SE Legacy plug-in window

The Neve 1073 Plug-Ins

The Neve 1073 Preamp and EQ Collection is comprised of three distinct plugins, as shown in Figure 78 on page 268 and the figures above. Although the controls are nearly identical, each plug-in has its own features and benefits.

Neve 1073 The Neve 1073 is based on a vintage "golden unit" channel module pulled from an original Neve 8014 console, including the original P&G output attenuating fader.

UA's Neve 1073 provides the *only* authentic, end-to-end circuit model of the class-A preamp and EQ circuit. An extremely detailed model was made of the 1073, starting with a Marinar input transformer model (and real physical impedance switching when used with Apollo's Unison technology). The transformer stage is followed by the Neve dual-transistor preamp (AKA "Red Knob") model with non-clipped and clipped nonlinear behaviors, such as characteristic asymmetric and dynamic duty-cycle clipping.

The three-band active EQ's filter interactions and internal amp clipping behaviors are also modeled, along with the passive low cut filter and the EQ's loading of the preamp output. The plug-in also captures the non-linear behaviors of the 1073's post-fader output amplifier, the output transformer, and much more. There are a total of ten different areas where the circuit can clip.

Neve 1073 Legacy	When physical amplification is not required or circuit non-linearites are not desirable, the 1073 Legacy EQ provides a spot-on linear emulation of the 1073's three-band EQ and passive cut filter, complete with modeled filter interaction.
	Because the Neve 1073 Legacy does not include nonlinearities of the EQ, nor modeling of the input and output stages, it uses significantly less UAD DSP re- sources than the newer Neve 1073. The Neve 1073 Legacy can be even more desirable than the Neve 1073 when a very clean sound is desired.
Neve 1073SE Legacy	The Neve 1073SE Legacy is nearly identical to the Neve 1073 Legacy but because this plug-in is not upsampled, it provides excellent UAD DSP efficiency.
	The Neve 1073SE Legacy interface is differentiated from the Neve 1073 Leg- acy by color and the module name. The 1073SE is black instead of the 1073's dark blue, and the module name on the lower right of the interface panel includes the "SE" suffix after 1073.
Control Differences	The following parameters are unique to Neve 1073 and unavailable with Neve 1073 Legacy and Neve 1073SE Legacy:
	 Unison Technology Mic/Line Input Select
	• Mic Gain
	Impedance Pad
	• Level
	• Output
Unison™ Integration	The Neve 1073 features Unison technology for integration with the mic preamp hardware in Universal Audio's Apollo audio interfaces. With Unison, Apollo's ultra-transparent mic preamps inherit all of the unique sonics, input characteristics, and features of the Neve 1073 hardware preamp.
	Note: Unison is active only when the Neve 1073 is inserted in the unique IN- PUT insert within Apollo's Console application. For complete Unison details,

see the Apollo Software Manual.

Realistic Tandem Control

Unison facilitates seamless interactive control of Neve 1073 plug-in settings using Apollo's digitally-controlled panel hardware and/or the plug-in interface. All equivalent preamp controls (gain, pad, polarity) are mirrored and bidirectional. The preamp controls respond to adjustments with precisely the same interplay behavior as the Neve 1073 hardware, including gain levels and clipping points.

Hardware Input Impedance

All Apollo mic preamps feature variable input impedance in analog hardware that can be physically changed by Unison plug-ins for physical, microphone-to-preamp resistive interaction. This impedance switching enables Apollo's preamps to physically match the emulated unit's input impedance, which can significantly impact the sound of a microphone. Because the electrical loading occurs on input, prior to A/D conversion, the realism is faithful to the original target hardware preamp.

Tactile Gain Staging

Apollo's front panel preamp knob can independently adjust the gain and level parameters available within the Unison plug-in via Gain Stage Mode. The gain stage being adjusted can be remotely switched via Apollo, so the gain levels and their associated colorations can be tuned from the hardware knob for precise physical tactile control, all without using the Unison plug-in's software interface.

Note: Unison technology is not available with Neve 1073 Legacy or Neve 1073SE Legacy.

Artist Presets The Neve 1073 includes artist presets from prominent Neve 1073 users. The artist presets are in the internal factory bank and are accessed via the host application's preset menu. The artist presets are also placed by the UAD installer so they can be used within Apollo's Console application. The presets can be loaded using the Settings menu in the UAD Toolbar (see "Using UAD Powered Plug-Ins" in Chapter 7 of the UAD System Manual).

This plug-in includes additional artist presets that are not available in the internal factory bank. These additional presets can also be accessed using the Settings menu in the UAD Toolbar.

Neve 1073 Latency	The Neve 1073 and Neve 1073 Legacy plug-ins use an internal upsampling technique to achieve sonic design goals. The upsampling results in a slightly larger latency than most other UAD plug-ins (between 0 and 88 samples, depending on the plug-in and sample rate).
	pending on the plug-in and sample rate).

These additional samples are automatically compensated by modern host DAWs. The Neve 1073SE is not upsampled; it does not have any extra latency. See Upsampled Plug-Ins for more information.

Neve 1073 Controls

All control descriptions apply to Neve 1073, Neve 1073 Legacy, and Neve 1073SE Legacy unless specifically noted otherwise.

Input Knob Overview The Input knob operates differently with the Neve 1073 which features full input stage modeling, and the Neve 1073/1073SE Legacy plug-ins which do not model the input stage.

Neve 1073

The Input Gain control (aka the "Red Knob") adjusts the input gain for both the mic preamp input and the line input. The gain parameter being controlled (mic or line) is switched by clicking the MIC or LINE text buttons, or by clicking the desired value in the opposite gain range.

When the MIC/LINE input is switched, the knob position changes to the gain range for the input, as shown in Figure 81 below.

Figure 81. Neve 1073 Mic/Line input select buttons and gain knob control ranges

Tip: The unusual "negative value" numbering originally used by Neve are based on sensitivity instead of gain. For example, if an input has a sensitivity of –80 dB, the input sensitivity knob on the 1073 would be set to –80 dB to match.

The mic input gain and line input gain are actually two separate parameters, as shown in Figure 82 below. Unlike the original hardware, the knob is constrained to control only one gain parameter without switching to the other input type.

UAD Nev	/e 1073	
Input Select:	💽 Line	Mic
Impedance:	🔵 Lo	💿 Hi
Pad:	💿 0 dB	🔵 -20 dB
Line Gain:	L 0 dB	\$
Mic Gain:	M -20 dB	\$

Figure 82. Neve 1073 in controls view showing the separate Mic and Line parameters

Neve 1073 Legacy and Neve 1073SE Legacy

The Input Gain control sets the level at the input of these plug-ins. Separate Mic/Line gain controls are unavailable because these plug-ins do not feature input stage modeling.

Input Select Input Select determines which input (mic or line) is being controlled with the Gain knob. To change the input gain being controlled, click the MIC or LINE text to switch to that input.

Tip: Input Select can also be switched by clicking any of the "dots" or gain value labels in the range for the input type.

When Input Select is changed, the Gain knob changes to use only the range for that input type (as shown in Figure 81 on page 272).

Like the hardware, the Neve 1073 plug-in easily facilitates sending Line level signal through the "virtual" Mic input, which allows creative use of distortion to color signals. This is the equivalent of routing a line level signal into a mic level input, so a large jump in gain is expected.

Important: Use caution when switching to Mic from Line, as output levels can increase significantly (as they would with any hardware preamp).

When Neve 1073 is used in a Unison insert within Apollo's Console application, software and hardware control of Input Select is mirrored. Input Select can be changed within the plug-in interface, with Console's MIC/LINE buttons, or with Apollo's hardware buttons (MIC/LINE on Apollo, or INPUT on Apollo Twin).

Note: Input Select is unavailable with the Legacy 1073/1073SE.

Line Gain Neve 1073

Line Gain has a range of 30 dB, available in 5 dB increments. Line Gain can only be adjusted when Input Select is set to LINE mode.

Like the original hardware, gain is *increased* as the knob is rotated *counter-clockwise* in the plug-in interface. However:

- In Unison mode, Line Gain is increased by turning Apollo's preamp level knob clockwise.
- In Controls View mode, Line Gain is increased by moving the control slider from left to right.

Note: When Line Gain is set to the OFF position, UAD DSP usage is reduced (unless UAD-2 LoadLock is enabled).

When Neve 1073 is used in a Unison insert within Apollo's Console application and Line Gain is set to the OFF position, the signal is muted. This is how the original hardware behaves. UAD DSP usage is not reduced in the OFF position in Unison mode.

Neve 1073 Legacy and Neve 1073SE Legacy

This control sets the level at the input of these plug-ins. The available continuous gain range is 30 dB.

Separate Mic/Line gain controls are unavailable because these plug-ins do not feature input stage modeling.

When the knob is in the OFF position, all plug-in process-

ing is disabled and UAD DSP usage is reduced (unless UAD-2 DSP LoadLock is enabled).

Tip: Clicking the OFF screen label toggles between OFF and the previously set Input Gain value. You can also click the Neve logo to toggle between OFF and the previous state. **Mic Gain** Mic Gain has a range of 60 dB, available in 5 dB increments. To increase the mic input gain, rotate the knob clockwise.

Mic Gain can only be adjusted when Input Select is set to MIC mode.

When Neve 1073 is used in a Unison insert within Apollo's Console application and Mic Gain is set to the OFF position, the signal is muted. This is how the original hardware behaves. UAD DSP usage is not reduced in the OFF position in Unison mode.

Note: Mic Gain is unavailable with the Legacy 1073/1073SE.

Mic Z (Impedance)

The impedance of the mic input is set with the Mic Z switch. The modeled input impedances have subtle effects on the signal color and response (even when not used in Unison

mode).

Note: Mic Z is unavailable with the Legacy 1073/1073SE.

L0

When set to LO, the mic input impedance is 300 Ohms.

HI

When set to HI, the mic input impedance is 1.2K Ohms.

Note: Mic Z is not available for line input, or when used with Apollo's Hi-Z input in Unison mode. In these cases, the control cannot be switched.

With the original hardware, most studios leave this control in the HI position (the default value in the plug-in). If an engineer chooses to access the LO setting on the hardware for a low output microphone (such as a ribbon mic), they need to crawl under the console to access the control on the back of the module.

Unison Impedance

When Neve 1073 is used in a Unison insert within Apollo's Console application, the hardware input impedance of the Apollo mic preamp is switched to match the value in the plug-in for physical, microphone-to-preamp resistive interaction.

Matching the microphone to the closest impedance value is generally recommended, but this parameter can be used creatively and will not harm equipment connected to the Apollo mic preamp. ⁻²⁰ When enabled, the mic input signal level is attenuated (lowered) by -20 dB.

Pad can be used to reduce signal levels when undesirable overload distortion is present at low preamp gain levels.

Note: Pad is not available for line input, or when used with Apollo's Hi-Z input in Unison mode. In these cases, the control cannot be switched.

When Neve 1073 is used in a Unison insert within Apollo's Console application, software and hardware control of PAD is mirrored. Pad can be switched within the plug-in interface, with Console's PAD button, or with Apollo's hardware PAD button.

The High Shelf knob offers approximately ±18 dB of smooth fixed frequency shelving equalization at 12 kHz.

Rotate the control clockwise to add the famous high-end Neve sheen, or counter-clockwise to reduce the treble response.

Tip: Click the "0" text label to return the control to the zero position. This shortcut is unavailable with Neve 1073/1073SE Legacy.

Midrange Band

High Shelf

The midrange band is controlled by dual-concentric knobs, delivering smooth semi-parametric midrange equalization.

The response for this band has a dependence on the bandwidth as the gain is adjusted. At higher center frequencies, the Q goes up, for a more focused peak.

The inner knob controls the band gain, and the outer ring selects the frequency or band disable. These two controls are detailed below.

Midrange Gain

The equalization gain for the midrange band is selected with the inner knob of the dual-concentric control. The available range is approximately ± 18 dB.

Tip: Click the "0" text label to return the control to the zero position. This shortcut is unavailable with Neve 1073/1073SE Legacy.

Pad

Midrange Frequency

The Mid frequency is selected with the outer ring of the dual-concentric knob controls. The ring control can be dragged with the mouse, or click directly on the text labels to specify a frequency or disable the Mid band.

Tip: Click the midrange symbol (at lower right of knob) or "KHz" label (at lower left of knob) to cycle through the available values. Shift + click to step back one frequency.

The available midrange center frequencies are 360 Hz, 700 Hz, 1.6 kHz, 3.2 kHz, 4.8 kHz, 7.2 kHz, and OFF. When OFF is specified, the band is disabled.

The low frequency band is controlled by dual-concentric knobs, delivering smooth shelving equalization.

The inner knob controls the band gain, and the outer ring selects the frequency or band disable. These two controls are detailed below.

Low Gain

The equalization gain for the low band is selected with the inner knob of the dual-concentric control. The available range is approximately ± 15 dB.

Rotate the control clockwise to boost the selected low band frequency, or counter-clockwise to reduce the bass response.

Tip: Click the "0" text label to return the control to the zero position. This shortcut is unavailable with Neve 1073/1073SE Legacy.

Low Frequency

The Low frequency is selected with the outer ring of the dual-concentric knob controls. The ring control can be dragged with the mouse, or click directly on the "silkscreen" text to specify a frequency or disable the Low band.

Tip: Click the low shelf symbol (at lower right of knob) or "Hz" label (at lower left of knob) to cycle through the available values. Shift + click to step back one frequency.

The available low band center frequencies are 35 Hz, 60 Hz, 110 Hz, 220 Hz, and OFF. When OFF is specified, the band is disabled.

Low Band

This knob specifies the fixed frequency of the high pass (low cut) filter. This filter has an 18 dB per octave slope.

The available frequencies are 50 Hz, 80 Hz, 160 Hz, 300 Hz, and OFF. When OFF is specified, the high pass filter is disabled.

Note: Click the high pass symbol (at lower right of knob) or "Hz" label (at lower left of knob) to cycle through the available values. Shift + click to step back one frequency.

- The filter is always in circuit, even when the EQL switch is disabled.
- When toggling the filter enable state with the hardware button on Apollo, the last set value is toggled.
- **Phase** The PHASE button inverts the polarity of the signal. When the switch is engaged (the darker "in" position), the phase is inverted. Leave the switch in the disengaged (the lighter "out" position) for normal phase.

When the plug-in is used in a Unison insert within Apollo's Console application, software and hardware control of PHASE is mirrored. Polarity can be inverted within the plug-in interface, with Console's polarity button, or with Apollo's hardware polarity button.

EQL

EQL The equalizer is engaged when the EQL switch is engaged (the darker "in" position). To disable the EQ, disengage the switch (the lighter "out" position).

The default position is disabled. Click the button to toggle the state.

UAD DSP usage is reduced when the EQ is bypassed with this control (unless UAD-2 DSP LoadLock is enabled).

In the hardware 1073, the audio is still slightly colored even when the EQL switch is disengaged and the EQ settings are in their "flat" positions. This is due to the fact that the signal is still passing through its circuitry.

More notably, all of the filter bands (except High Pass) can have an effect on the clipping behaviors of the Neve 1073 (except Legacy versions), even when EQL is disengaged. Therefore, the EQ values can have a significant effect on the signal when the EQ is "disabled" via the EQL switch.

If a true bypass is desired, use the OFF position of the Power switch (Neve 1073) or the OFF position of the Line Gain control (Neve 1073/1073SE Legacy).

Level

Level controls the signal level at the output stage of the module. The circuitry of an original Neve console fader was modeled for this control.

The available range is from $-\infty$ dB (off) to +10 dB. Unity gain is at the zero position. Raising Level above 0 dB can cause output amplifier clipping.

Tip: Click the "0" text labels to return Level to 0 dB.

Output

Output adjusts the signal level at the output of the plug-in without effecting the sonic character of the signal. The available range is ± 24 dB.

This control, which does not exist on the original hardware, facilitates the ability to maximize color of the overall signal. For ex-

ample, Gain and Level can be cranked for more distortion, while lowering Output to normalize levels.

Note: If comparing the Neve 1073 plug-in (when it is not in Unison mode) with the original hardware, set Output to +10.8 dB so software and hardware levels will match.

Power

Power is the plug-in bypass control. When set to OFF, emulation processing is disabled and DSP usage is reduced (if UAD-2 DSP LoadLock is inactive).

Power is useful for comparing the processed settings to the original signal.

CHAPTER 28

Neve 1081 Equalizer

Overview

The Neve 1081 channel module was first produced in 1972 by Neve, and was used to provide the mic/line amp and EQ sections in consoles such as the Neve 8048. Vintage 8048 consoles, with 1081 modules, are still in wide use today at classic facilities such as The Village in Los Angeles, and have been chosen by artists ranging from The Rolling Stones to The Red Hot Chili Peppers.

Universal Audio's Neve 1081 EQ delivers the same sonic experience as its analog cousin with exacting detail. The 1081 EQ also includes a DSP optimized 1081SE EQ for higher instance counts.

Neve 1081 Screenshot

Figure 83. The Neve 1081 plug-in window

Neve 1081 and 1081SE Controls

Overview The Neve 1081 channel module is a four-band EQ with high and low cut filters. The 1081 features two parametric midrange bands, with "Hi-Q" selections for tighter boosts or cuts. Both the high and low shelf filters have selectable frequencies and may be switched to bell filters. Other features include a -20 to +10 dB input gain control, phase reverse, and EQ bypass.

The bands are arranged and grouped as in Figure 84 below. The bands feature dual-concentric controls. For each of the main bands, the inner knob controls the gain while the outer ring controls the frequency. The low and high cut filters are grouped as one knob/ring set, but they are actually two independent filters.

Band Layout

Figure 84. Neve 1081 band control layout

Input Gain

The Input Gain control sets the level at the input of the plug-in. The range is from -20 dB to +10 dB.

When the Input Gain knob "snaps" to the OFF position, plug-in processing is disabled and UAD DSP usage is reduced (unless UAD-2 DSP LoadLock is enabled).

Note: Clicking the OFF screen label toggles between

OFF and the previously set Input Gain value. You can also click the Neve logo to toggle between OFF and the previous state.

The high band delivers smooth high frequency shelving or peak equalization. The inner knob controls the band gain, and the outer ring selects the frequency or band disable.

High Gain

The equalization gain for the high band is selected with the inner knob of the dual-concentric control. Rotate the control clockwise to add the famous high-end Neve sheen, or counter-clockwise to reduce the treble response. The available range is approximately ±18 dB.

High Frequency

The high band frequency is selected with the outer ring of the dual-concentric knob controls. The ring control can be dragged with the mouse, or click directly on the "silkscreen" text to specify a frequency or disable the band.

Note: You can also click the shelving symbol above the knob to cycle through the available values, or shift + click to step back one frequency.

The available high band center frequencies are 3.3 kHz, 4.7 kHz, 6.8 kHz, 10 kHz, 15 kHz, and OFF. When OFF is specified, the band is disabled. UAD DSP usage is not reduced when the band is OFF.

High Peak Select

The High Peak button switches the high band from a shelving EQ to a peaking EQ. The band is in shelf mode by default; it is in peak mode when the button is "down" (darker).

High-Mid Band

The high-midrange band delivers smooth high-mid frequency peak equalization with a choice of two bandwidths. The inner knob controls the band gain, and the outer ring selects the frequency or band disable.

High-Mid Gain

The equalization gain for the high-midrange band is selected with the inner knob of the dual-concentric control. The available range is approximately ±18 dB.

High-Mid Frequency

The high-midrange band frequency is selected with the outer ring of the dualconcentric knob controls. The ring control can be dragged with the mouse, or click directly on the "silkscreen" text to specify a frequency or disable the band.

Note: You can also click the midrange symbol below the knob to cycle through the available values, or shift + click to step back one frequency.

The available high-mid band center frequencies are 1.5 kHz, 1.8 kHz, 2.2 kHz, 2.7 kHz, 3.3 kHz, 3.9 kHz, 4.7 kHz, 5.6 kHz, 6.8 kHz, 8.2 kHz, and OFF. When OFF is specified, the band is disabled. UAD DSP usage is not reduced when the band is OFF.

High-Mid Q Select

The High Q button switches the response of the high-mid band from "normal" to a narrower bandwidth for a sharper EQ curve. The band is in normal mode by default; it's in high Q mode when the button is "down" (darker).

Low-Mid Band

The low-midrange band delivers smooth low-mid frequency peak equalization with a choice of two bandwidths. The inner knob controls the band gain, and the outer ring selects the frequency or band disable.

Low-Mid Gain

The equalization gain for the low-midrange band is se-

lected with the inner knob of the dual-concentric control. The available range is approximately ±18 dB.

Low-Mid Frequency

The low-midrange band frequency is selected with the outer ring of the dualconcentric knob controls. The ring control can be dragged with the mouse, or click directly on the "silkscreen" text to specify a frequency or disable the band.

Note: You can also click the midrange symbol below the knob to cycle through the available values, or shift + click to step back one frequency. The available low-mid band center frequencies are 220 Hz, 270 Hz, 330 Hz, 390 Hz, 470 Hz, 560 Hz, 680 Hz, 820 Hz, 1000 Hz,1200 Hz, and OFF. When OFF is specified, the band is disabled. UAD CPU usage is not reduced when the band is OFF.

Low-Mid Q Select

The High Q button switches the response of the low-mid band from "normal" to a narrower bandwidth for a sharper EQ curve. The band is in normal mode by default; it's in high Q mode when the button is "down" (darker).

Low Band

The low band delivers smooth low frequency shelving or peak equalization. The inner knob controls the band gain, and the outer ring selects the frequency or band disable.

Low Gain

The equalization gain for the low band is selected with

the inner knob of the dual-concentric control. The available range is approximately ± 18 dB.

Low Frequency

The low band frequency is selected with the outer ring of the dual-concentric knob controls. The ring control can be dragged with the mouse, or click directly on the "silkscreen" text to specify a frequency or disable the band.

The available low band center frequencies are 33Hz, 56 Hz, 100 Hz, 180 Hz, 330 Hz, and OFF. When OFF is specified, the band is disabled. UAD CPU usage is not reduced when the band is OFF.

Note: You can also click the shelving symbol above the knob to cycle through the available values, or shift + click to step back one frequency.

Low Peak Select

The Low Peak button switches the low band from a shelving EQ to a peaking EQ. The band is in shelf mode by default; it is in peak mode when the button is "down" (darker).

Cut Filters

The independent low and high cut filters are controlled by the dual-concentric knobs to the right of the low band (see Figure 84 on page 282). The controls specify the fixed frequency of the cut filter. The cut filters have an 18 dB per octave slope.

Click+drag the control to change the value, or click the "silkscreen" frequency values.

Note: You can also click the high cut/low cut symbols below the knob to cycle through the available values, or shift + click to step back one frequency.

High Cut

The inner (blue) dual-concentric knob controls the high cut filter. The available frequencies for the high cut filter are 18 kHz, 12 kHz, 8.2 kHz, 5.6 kHz, 3.9 kHz, and OFF. When OFF is specified, the high cut filter is disabled. UAD CPU usage is not reduced when OFF.

Low Cut

PH

The outer (silver) dual-concentric ring controls the low cut filter. The available frequencies for the low cut filter are 27 Hz, 47 Hz, 82 Hz, 150 Hz, 270 Hz, and OFF. When OFF is specified, the low cut filter is disabled. UAD CPU usage is not reduced when OFF.

Phase

The Phase (PH) button inverts the polarity of the signal. When the switch is in the "In" (lit) position, the phase is reversed. Leave the switch in the "Out" (unlit) position for normal phase.

EQ Enable

The equalizer is engaged when the EQ switch is in the "In" (lighted) position. To disable the EQ, put the switch in the "Out" (unlit) position. Click the button to togale the state.

In the hardware 1081, the audio is still slightly colored even when the EQ switch is in the Out position. This is due to the fact that the signal is still passing through its circuitry. Therefore, the signal will be slightly colored when this switch is in the Out position. UAD DSP usage is reduced when the EQ is bypassed with this control (unless UAD-2 DSP LoadLock is enabled). If a true bypass is desired, use the OFF position of the "Input Gain" on page 282 control.

Neve 1081SE

Figure 85. The Neve 1081SE plug-in window

Overview The UAD Neve 1081SE is derived from the UAD Neve 1081. Its algorithm has been revised in order to provide sonic characteristics very similar to the 1081 but with significantly less DSP usage. It is provided to allow 1081-like sound when DSP resources are limited. Nobody with "golden ears" will say it sounds exactly like the 1081, but it still sounds great and is very usable in most situations.

The 1081SE interface can be differentiated from the 1081 by color and the module name. The 1081SE is black instead of the 1081's dark blue, and the module name on the lower right of the interface panel includes "SE".

Neve 1081SE Controls The Neve 1081SE controls are exactly the same as the Neve 1081. Please refer to the Neve 1081 section for Neve 1081SE control descriptions (see "Neve 1081 and 1081SE Controls" on page 282).

Neve 1081 Latency

The Neve 1081 (but not the 1081SE) uses an internal upsampling technique to facilitate its amazing sonic quality. This upsampling results in a slightly larger latency than other UAD plug-ins. See See "Upsampled Plug-Ins" on page 563. for more information.

The Neve 1081SE does not require additional latency compensation because it is not upsampled.

Note: Compensating for Neve 1081 is not required if the host application supports full plug-in delay compensation throughout the signal path, or when it is used only on the outputs.

All visual and aural references to the Neve® 1073, 1081, 31102, 88RS, and 33609 products and all use of AMS-Neve's trademarks are being made with written permission from AMS-Neve Limited.

CHAPTER 29

Neve 31102 Console EQ

Overview

The Neve 8068 console, featuring the 31102 EQ, was used to hand-mix one of the best selling debut albums of all time; Appetite For Destruction by Guns-N-Roses. Artists ranging from Primus and Metallica to My Morning Jacket and The Red Hot Chili Peppers have also called on the distinct tone of the Neve 8068 and 31102 EQ in the studio. Universal Audio's officially licensed and endorsed Neve 31102 EQ plug-in delivers the same sonic experience as its analog cousin with exacting detail. Complete with its own distinct filter shaping and unmistakable sheen and bite, the 31102 provides another step in the evolution of classic Neve EQs. 3-band active EQ and High/Low filters offer enhanced tone-shaping possibilities and a feature complexity that sits squarely between its cousins, the 1073 and the 1081.

The Neve 31102/SE EQ is a three band (10, 12 and 16 kHz) high shelving EQ, a six frequency (7.2, 4.8, 3.2, 1.6, 0.7 and 0.35 kHz) peaking EQ with two Q types, a four frequency (220, 110, 60 and 35 Hz) low shelving EQ, a four frequency high pass filter (45, 70, 160 and 360 Hz) and five frequency (6, 8, 10, 14 and 16 kHz) low pass filter. Other features include a 30 dB range of Gain Trim, plus phase reverse and EQ bypass. The UAD Neve 31102 license also includes a DSP-optimized 31102SE "Special Edition" EQ for higher instance counts.

Neve 31102 Screenshot

Figure 86. The Neve 31102 plug-in window
Neve 31102 and 31102SE Controls

Input Gain

The Input Gain control sets the level at the input of the plugin, and doubles as a plug-in bypass control. The range is from -20 dB to +10 dB, and off.

When the Input Gain knob "snaps" to the off position, plug-in processing is disabled and UAD DSP usage is reduced.

Note: (UAD-2 only) UAD-2 DSP usage is reduced only when DSP LoadLock is disabled. If DSP LoadLock is enabled (the default setting), setting Input Gain to off will not reduce DSP usage.

Tip: Clicking the "off" screen label toggles between off and the previously set Input Gain value. You can also click the Neve logo to toggle between off and the previous state.

High Shelf The high shelf delivers smooth high frequency shelving equalization, controlled by dual-concentric knobs. The inner knob controls the band gain, and the outer ring selects the frequency or band disable.

High Shelving Gain

The gain for the high band is selected with the inner knob of

the dual-concentric control. Rotate the control clockwise to add the famous high-end Neve sheen, or counter-clockwise to reduce the treble response.

The available range is approximately ± 15 dB. The gain value is zero when the knob position indicator is pointing straight down.

High Shelving Frequency

The high shelving frequency is specified with the outer ring of the dual-concentric knob. The ring knob pointer can be dragged with the mouse, or click the shelving symbol above the knob to cycle through the available frequencies (shift+click to step back one frequency).

The available high shelving frequencies are 16 kHz, 12 kHz, 10 kHz, and off. When off is specified, the high shelf band is disabled. UAD DSP usage is not reduced when the band is off.

Midrange Band

The midrange band is controlled by dual-concentric knobs, delivering smooth semi-parametric midrange equalization with a choice of two bandwidths. The inner knob controls the band gain, and the outer ring selects the frequency or band disable.

Midrange Gain

The equalization gain for the midrange band is selected with the inner knob of the dual-concentric control. The available range is approximately ± 15 dB. The gain value is zero when the knob position indicator is pointing straight down.

Midrange Frequency

The midrange frequency is specified with the outer ring of the dual-concentric knob controls. The ring knob pointer can be dragged with the mouse, or click the peak/dip symbol above the knob to cycle through the available frequencies (shift+click to step back one frequency).

The available midrange center frequencies are 7.2 kHz, 4.8 kHz, 3.2 kHz, 1.6 kHz, 0.7 kHz, 0.35 kHz, and off. When off is specified, the band is disabled. UAD DSP usage is not reduced when the band is off.

High Q Select

The High Q button switches the response of the midrange band from "normal" to a narrower bandwidth for a sharper EQ curve. The band is in normal mode by default; it's in high Q mode when the button is "down" (darker).

Low Shelf

The low band is controlled by dual-concentric knobs, delivering smooth shelving equalization. The inner knob controls the band gain, and the outer ring selects the frequency or band disable.

Low Gain

The equalization gain for the low band is selected with the

inner knob of the dual-concentric control. The available range is approximately ± 15 dB. The gain value is zero when the knob position indicator is pointing straight down.

Rotate the control clockwise to boost the selected low band frequency, or counter-clockwise to reduce the bass response.

Low Frequency

The low frequency is selected with the outer ring of the dual-concentric knob controls. The ring knob pointer can be dragged with the mouse, or click the shelving symbol above the knob to cycle through the available frequencies (shift+click to step back one frequency).

The available low band center frequencies are 35 Hz, 60 Hz, 110 Hz, 220 Hz, and off. When off is specified, the band is disabled. UAD DSP usage is not reduced when off.

Cut Filters

The independent low and high cut filters are controlled by the dual-concentric knobs to the right of the low band. The controls specify the fixed frequency of each cut filter.

The knob pointers can be dragged with the mouse, or click the respective cut symbols above the knob (left symbol for low cut, right symbol for high cut) to cycle through the available frequencies (shift+click to step back one frequency).

High Cut

The inner (blue) dual-concentric knob controls the high cut filter. The available frequencies for the high cut filter are 18 kHz, 14 kHz, 10 kHz, 8 kHz, 6 kHz, and off. When off is specified, the high cut filter is disabled.

Low Cut

The outer dual-concentric ring controls the low cut filter. The available frequencies for the low cut filter are 45 Hz, 70 Hz, 160 Hz, 360 Hz, and off. When OFF is specified, the low cut filter is disabled.

Note: Each cut filter is disabled when its respective knob position indicator is pointing straight down. UAD DSP usage is not reduced when the cut filters are off.

Phase

The Phase (\emptyset) button inverts the polarity of the signal. The signal is inverted when the button is engaged (darker). Leave the button inactive (lighter) for normal phase.

EQL

The equalizer is engaged when the EQL switch is in the "In" (darker) position. To disable the EQ, put the switch in the "Out" (lighter) position. Click the button to toggle the state.

In the hardware 31102, the audio is still slightly colored even when the EQL switch is in the Out position. This is due to the fact that the signal is still passing through its circuitry. Therefore, the signal will be slightly colored when this switch is in the Out position. UAD DSP usage is reduced when the EQ is by-passed with this control (unless UAD-2 DSP LoadLock is enabled).

If a true bypass is desired, use the OFF position of the Input Gain control ("Input Gain" on page 289).

Neve 31102SE

Figure 87. The Neve 31102SE plug-in window

Overview The UAD Neve 33102SE is derived from the UAD Neve 31102. Its algorithm has been revised in order to provide sonic characteristics very similar to the 31102 but with significantly less DSP usage. It is provided to allow 31102-like sound when DSP resources are limited. Nobody with "golden ears" will say it sounds exactly like the 31102, but it still sounds great and is very usable in most situations.

The 31102 interface can be differentiated from the 31102 by color and the module name. The 31102SE background is black instead of the 31102's dark blue, and the module name on the lower right of the interface panel includes "SE".

Neve 31102SE
ControlsThe Neve 31102SE controls are exactly the same as the Neve 31102. Please
refer to "Neve 31102 and 31102SE Controls" on page 289 for Neve
31102SE control descriptions.

Neve 31102 Latency

The Neve 31102 (but not the 31102SE) uses an internal upsampling technique to facilitate its amazing sonic quality. This upsampling results in a slightly larger latency than other UAD plug-ins. The latency and its compensation is identical to that of the other UAD Neve EQ's. See See "Upsampled Plug-Ins" on page 563. for more information.

The Neve 31102SE does not require additional latency compensation because it is not upsampled.

Note: Compensating for Neve 31102 is not required if the host application supports full plug-in delay compensation throughout the signal path, or when it is used only on the outputs.

One Neve 31102 EQ hardware module and 31102s installed in a Neve 8068 console

All visual and aural references to the Neve® 1073, 1081, 31102, 88RS, and 33609 products and all use of AMS-NEVE's trademarks are being made with written permission from AMS-Neve Limited.

CHAPTER 30

Neve 33609 Compressor

Overview

Derived from the original Neve 2254 compressor, circa 1969, the 33609 stereo bus compressor/limiter utilizes a bridged-diode gain reduction circuit and many custom transformers. The uniquely musical character of this circuit made the 33609 a studio standard since its release. The UAD Neve 33609 is the only Neve-sanctioned software recreation of the Neve 33609 (revision C). Every detail of the original unit is captured, and matches its hardware counterpart with absolute precision. The 33609 plug-in includes a DSP-optimized 33609SE which allows for higher instance counts.

The completely step-controlled 33609 is made up of separate compression and limiter sections, each with their own threshold, recovery and bypass controls. Two of the recovery selections for each section are dedicated to a program dependent auto release. The compressor section also offers five ratio selections and 20 dB make-up gain, while the limiter offers a fast or slow attack. The mono/stereo switch couples and decouples the left and right gain reduction elements.

The UAD Powered Plug-In version of the Neve 33609 adds a few control enhancements not found on the hardware: An additional stepped output control with 20 dB of gain, a link switch allowing ganged left/right control of all parameters, and a headroom switch, which allows the DAW user to take advantage of the full range of 33609 gain coloration.

Neve 33609 Screenshot

Figure 88. The Neve 33609 plug-in window

Operation

The UAD Neve 33609 is a two-channel device capable of running in stereo or dual-mono modes. The active mode is determined by the mono/stereo switch (see "Mono/Stereo" on page 299). When the 33609 is used in a mono-in/mono-out configuration, the channel 2 controls are disabled.

Each channel consists of a compressor and a limiter. Each of these functions has its own separate group of controls. Since the controls for each of the two channels are identical, they are detailed only once.

Signal Flow In the 33609, the output of the compressor is fed to the input of the limiter. Like the original hardware, the signal does not flow "from the left to the right" of the interface. Understanding this signal flow will help you obtain a more predictable result (see Figure 89 below).

Figure 89. Signal flow within UAD Neve 33609

Modeling The UAD Neve 33609 models all aspects of the original 33609 hardware, including the desirable harmonic distortion characteristics. These qualities are more prominent at higher input levels (see "Headroom" on page 301" for more info).

When the compressor and limiter are both disabled, some (good) coloration of the signal occurs, just like the hardware. If a true bypass is desired, use the power switch ("Power" on page 303) to disable the plug-in.

- **Technical Article** The article "Ask the Doctors: Modeling of the Neve 33609 compressor/limiter" contains interesting technical details about the 33609. It is available at our online webzine:
 - http://www.uaudio.com/webzine/2006/august/index2.html

Neve 33609 and 33609SE Controls

Limiter

Controls in this section only function when the limiter is enabled with the "limit In" switch (the Power switch must also be on).

Note: The compressor precedes the limiter (see "Signal Flow" on page 295).

Limiter Threshold	Threshold determines how much limiting will occur. When the input signal exceeds the threshold level, the signal above the threshold is limited. A smaller value results in more limiting. The available range is from +4 dB to +15 dB, in 0.5 dB increments.
	If the compressor is enabled, the Gain control in the compressor section ("Compressor Gain" on page 298) will affect the input level into the limiter. In this case, the compressor gain can affect the limiter threshold response.
Limiter Recovery	Recovery (release) is the time it takes for the limiter to stop processing after the signal drops below the threshold value. The available values (in milliseconds) are 50, 100, 200, 800, a1, and a2.

The automatic settings (a1 and a2) are program dependant. The value for a 1 can be as fast as 40ms, but after a sustained period of high signal level, the period is \approx 1500ms. The value for a2 can be as fast as 150ms, but after a sustained period of high signal level, the period is \approx 3000ms.

- **Limiter In** This toggle switch enables the limiter portion of the plug-in. The limiter has no effect unless this switch is in the "In" (down) position.
- Attack Attack determines how fast limiting will engage when the signal exceeds the limiter threshold. The Fast setting is 2 milliseconds, and the Slow setting is 4 milliseconds.

Compressor

Controls in this section only function when the compressor is enabled with the "compress In" switch (the Power switch must also be on).

Note: The compressor precedes the limiter (see "Signal Flow" on page 295).

Compressor
ThresholdThreshold determines how much compression will occur. When the input sig-
nal exceeds the threshold level, the compressor engages. A smaller value re-
sults in more compression. The available range is from -20 dB to +10 dB, in
2 dB increments.Compressor
RecoveryRecovery (release) is the time it takes for the compressor to stop processing af-
ter the signal drops below the threshold value. The available values (in milli-
seconds) are 100, 400, 800, 1500, a1, and a2.

The automatic settings (a1 and a2) are program dependant. The value for a1 can be as fast as 40ms, but after a sustained period of high signal level, the period is \approx 800ms. The value for a2 can be as fast as 150ms, but after a sustained period of high signal level, the period is \approx 1500ms.

Compressor Gain	This makeup gain control increases the signal level out of the compressor to compensate for reduced levels as a result of compression. The available range is 0 to +20 dB, in 2 dB increments.
	Make sure to adjust the Gain control <i>after</i> the desired amount of compression is achieved with the Threshold control. The Gain control does not affect the amount of compression.
	Note: If the limiter is also enabled, this gain is applied before the limiter stage.
Ratio	This control determines the compressor ratio. The available values are 1.5:1, 2:1, 3:1, 4:1, and 6:1, selectable in discrete increments.
Compressor In	This toggle switch enables the compressor portion of the plug-in. The compressor has no effect unless this switch is in the "In" (down) position.

Other Controls

The interface elements that are not directly contained within the compressor or limiter are detailed below.

Output Gain This control is a software-only addition not found on the original hardware. It is an overall makeup gain stage at the output of the plug-in to compensate for reduced levels as a result of compression and/or limiting. The available range is -2 to +20 in 1 dB increments.

Gain ReductionThe Gain Reduction Meters indicate the amount of gain reduction that is oc-
curring in dB. There is one meter for each channel. The gain reduction dis-
played is the total reduction of the limiter plus the compressor.

Note: The meter indicator moves farther to the right as more gain reduction is occurring. This meter behavior is opposite that of many compressors.

Link This switch is a software-only addition that allows the two sets of controls for each channel to be linked for ease of operation when both channels require the same values, or unlinked when dual-mono operation is desired. The Link parameter is stored within presets and can be accessed via automation.

Unlink

When set to unlink (up position), the controls for channels one and two are completely independent. Unlink is generally used in mono mode. When unlinked, automation data is written and read by each channel separately.

Note: When unlink is switched to link, channel 1 controls are copied to channel 2. Control offsets between channels are lost in this case.

Link

When set to link (down position), modifying any channel one or channel two control causes its adjacent stereo counterpart control to snap to the same position (channel 1 & 2 controls are ganged together in link mode).

When link is active, automation data is written and read for channel one only. In this case, the automation data for channel one will control both channels.

Note: When link is active, changing channel two parameters from a control surface or when in "controls only" (non-GUI) mode will have no effect.

Mono/Stereo The Neve 33609 can operate in true stereo or dual-mono mode. This switch determines the active mode.

Mono

In mono mode, channels 1 and 2 are completely independent and the 33609 functions as a dual-mono device, each channel with its own compressor and limiter.

Note: To read and write automation data for both channels independently when in mono mode, link mode must be disabled.

Stereo

In stereo mode, the left channel is fed to the channel one compressor, and the right channel is fed to the channel two compressor. The two compressors are constrained so that they both compress the same amount at any instant. This prevents transients which appear only on one channel from shifting the image of the output. Any big transient on either channel will cause both channels to compress. The amount of compression will be similar to the amount of compression for a transient which appears on both channels at the same time.

In stereo operation the controls for channels 1 and 2 are independent and can be set separately. Generally, the channel with the "most processing occurring" controls the processing for the other channel. For example, if the same signal is fed to both channels in stereo mode and channel 1 has a lower threshold setting than channel 2, the channel 1 threshold value is used for both channels. Similarly, if channel 1 were disabled (using "In" switches), channel 2 settings would be used because "more processing" occurs with the channel 2 settings. It's not always so simple though, as in the following cases:

- If you feed the same signal into both channels, you can have a lower threshold with a lower ratio on one channel, and a higher threshold with a higher ratio on the other channel. In this case, you will get a double knee, with the lower ratio being used between the knees, and the higher ratio above both knees.
- If you feed the same signal into both channels, you can have a lower threshold with a faster release on one channel, and a higher threshold with a slower release in the other channel. In this case, you will get a two-stage release after a transient, with the first channel releasing at the fast rate until you get down to where the other one is; then the release will continue at the slower rate.

Expert Question

Is there any reason I would want to use stereo mode and still have the settings for the two channels different?

Yes. Linking the sidechains simply prevents left-right image shifting. Threshold, attack, and recovery can be set independently to cause the compressor to be more sensitive to instruments which are panned to one side or the other. Output controls can be set separately in order to correct an overall image shift at the output.

Headroom Background

The hardware Neve 33609 can accept an analog signal level of approximately +26 dBu before undesirable signal clipping occurs. As the signal increases up to this point however, desirable audio-path nonlinearities and "good" harmonic distortion characteristics occur. This musically pleasing "warmth" at higher levels is what gives the unit much of its revered sonic character. Because analog mixing consoles can typically output high signal levels, audio engineers often take advantage of the ability to "push" the hardware 33609 into the colorful arena.

This complete pallet of sonic nuance, including the dynamic input response, is captured in the UAD Neve 33609 model. The plug-in is calibrated internally so that 0 dBFS at its input is equivalent to an input level of approximately +26 dBu on the 33609 hardware, where the coloring is more prominent. The result is that a typical signal within a DAW will drive the UAD Neve 33609 into these "virtual" higher levels, resulting in fairly high amounts gain reduction.

Headroom Switch

The Headroom switch is provided to accommodate applications where high amounts of gain reduction are not desired. Headroom simply lowers the internal operating level so that the plug-in is not "pushed" into gain reduction as much.

Headroom can be set to 22 dB, 18 dB, or 14 dB. At 22 dB, signals will push the plug-in into gain reduction (and more non-linearity and "good" harmonic distortion) more easily. Set the switch to a lower value when less gain reduction and color is desired.

The numbers on the switch indicate where 0 dBFS falls relative to nominal +4 dBu. For example, with 22 dB of headroom, 0 dBFS corresponds to +4 dBu + 22 dB = 26 dBu. With 18 dB of headroom, 0 dBFS corresponds to +4 dBu + 18 dB = 22 dBu. The headroom selected will cause the plug-in to behave as though it were a hardware 33609 connected to a nominal +4 dBu interface with the selected amount of headroom. Industry standards for most DAW interfaces are +14 dB and +18 dB headroom. The +22 dB setting approximates some analog mixing environments, and allows the entire useful dynamic range of the 33609 to be exercised.

The following settings are application guidelines for the Headroom switch:

22 dB

Typical starting point for individual track inserts where maximum gain reduction is desired. This setting is equivalent to having a real hardware 33609 connected to a +4 interface with +22 dB headroom.

18 dB

Typical starting point when used on a buss or group where nominal gain reduction is desired. This setting is equivalent to having a real hardware 33609 connected to a +4 interface with +18 dB headroom.

14 dB

Typical starting point for mastering where minimal gain reduction is desired. This setting is equivalent to having a real hardware 33609 connected to a +4 interface with +14 dB headroom.

Note: Keep in mind there are no hard and fast rules. Use the above recommendations as guidelines and feel free to experiment with the various positions of the headroom switch regardless of the audio source. If it sounds good, use it!

Factory Presets The UAD Neve 33609/33609SE includes a bank of factory presets. These presets can be useful starting points for your particular source audio.

The factory preset names begin with MSTR, BUSS, or TRAK. These indicate the setting of the headroom parameter. (14 dB, 18 dB, and 22 dB respectively).

Mastering (MSTR) presets are optimized for mixed program material that is already at a relatively high level.

Buss/group (BUSS) presets are optimized for subgroups of audio, such as a drum group or vocal group. This type of application often has lower levels than full mixes, but higher levels than a track insert.

Track (TRAK) presets are optimized for track inserts where signal levels typically aren't as hot as groups or outputs.

The preset names are guidelines and not rules. In many cases, you can use any preset on any source with good results. You will probably need to adjust the threshold and/or gain controls to obtain the optimum results with your particular source audio. **Power** The Power switch determines whether the plug-in is active. This is useful for comparing the processed settings to the original signal, or to bypass the plug-in to reduce the UAD DSP load (load is not reduced if *UAD-2 DSP LoadLock* is enabled). Toggle the switch to change the Power state; the switch is illuminated in red when the plug-in is active.

Note: You can click-hold the power switch then drag it like a slider to quickly compare the enabled/disabled state.

Neve 33609SE

Figure 90. The Neve 33609SE plug-in window

Overview The UAD Neve 33609SE is derived from the UAD Neve 33609. Its algorithm has been revised in order to provide sonic characteristics very similar to the 33609 but with significantly less DSP usage. It is provided to allow 33609-like sound when DSP resources are limited. Nobody with "golden ears" will claim it sounds exactly like the 33609, but it still sounds great and is very usable in most situations.

The 33609SE interface can be differentiated from the 33609 by color and the module name. The 33609SE background is black instead of the 33609's blue/grey, and the module name below the link switch includes "SE".

Neve 33609SE Controls The Neve 33609SE controls are exactly the same as the Neve 33609. Please refer to the Neve 33609 section for Neve 33609SE control descriptions (see "Neve 33609 and 33609SE Controls" on page 296).

Neve 33609 Latency

The Neve 33609 (but not the 33609SE) uses an internal upsampling technique to facilitate its amazing sonic quality. This upsampling results in a slightly larger latency than other UAD plug-ins. See See "Upsampled Plug-Ins" on page 563. for more information.

Note: The Neve 33609SE does not require additional latency compensation because it is not upsampled.

Note: Compensating for Neve 33609 is not required if the host application supports full plug-in delay compensation throughout the signal path, or when it is used only on the outputs.

All visual and aural references to the Neve® 1073, 1081, 31102, 88RS, and 33609 products and all use of AMS-NEVE's trademarks are being made with written permission from AMS-Neve Limited.

CHAPTER 31

Neve 88RS Channel Strip Collection

Neve's premier analog console emulation – featuring Unison™ mic preamp modeling

The Neve 88 Series is a paragon of large-format analog console design. Introduced in 2001, the 88 Series is renowned for its startling depth, airiness, and clarity — deftly encompassing the best of all Neve designs that came before it. Not surprisingly, Neve 88 Series consoles are found in some of the world's finest recording studios and scoring stages, including Skywalker Ranch, Capitol, Abbey Road, and United/Ocean Way recording.

Now for the first time, you can track through an authentic emulation of this modern masterpiece — complete with its famous mic/line preamp, cut filters, dynamics, four-band EQ, plus post-fader output amplifier — exclusively for UAD-2 hardware and Apollo interfaces.

Now you can: • Sculpt your mix with Neve's premium large-format analog console sound

- Get the clarity and openness of Neve's famous 88RS transformer-based mic preamp
- Shape your signals with legendary Neve 88RS Formant Spectrum EQ and Dynamics sections
- Control Apollo interface mic preamp gain staging and impedance directly from the plug-in via Unison[™] technology
- Mix with artist presets from Jimmy Douglass, Andrew Dawson, Joey Waronker, and Ryan West
- Create a modern Neve analog console in your DAW

The only end-to-end Neve 88RS Channel Strip Circuit Emulation

Universal Audio's all-new Neve 88RS Channel Strip for Apollo and UAD-2 precisely emulates the unique circuit behaviors of Neve's flagship large-format mixer. Modeling the mic/line preamp, cut filters, dynamics, four-band EQ, plus post-fader output amplifier with fanatical detail, the Neve 88RS Channel Strip plug-in replicates the luxurious sonics and high-fidelity sound of Neve's ultimate mixing console.

Unison Technology for Apollo Interfaces

Harnessing UA's groundbreaking Unison technology, the Neve 88RS Channel Strip Collection gives you all of the 88RS mic/line preamp's impedance, gain stage "sweet spots," and circuit behaviors that have made it the modern benchmark in analog preamp design. The secret is Unison's bi-directional control and communication from the Neve 88RS plug-in to the physical mic preamps in Apollo. And the results are nothing short of spectacular.

Sculpt with Neve's Formant Spectrum EQ

The 88RS is outfitted with broad range, minimum-phase 12 dB high and low cut filters to shape any signal during tracking or mixdown. In addition, Neve's famed Formant Spectrum four-band EQ, perfect for ambitious tonal strokes or precise surgery, offers classic Neve color on any source.

Crush or Expand with Neve 88RS Dynamics

With versatile and musical VCA-type limit/compress and gate/expand modules, the 88RS' dynamics sections can precisely tailor any source; transparently smoothing a lead vocal, bringing excitement and immediacy to a percussion bus, or even providing frequency-dependent gain reduction for deessing.

Add Depth and Openness with any UAD-2 hardware

Of course, the Neve 88RS Channel Strip Collection isn't just for Apollo owners. UAD-2 owners can use the Neve 88RS Channel Strip for amplification, EQ tone shaping, dynamics control, or adding the Neve sheen to any source, without going outside the box.

With the Neve 88RS Channel Strip's complete console channel emulation, plus the included DSP-lite Neve 88RS Channel Strip Legacy, you can craft your projects with the stunning analog clarity the 88RS is famous for.

Figure 91. The Neve 88RS plug-in window

The Neve 88RS Plug-Ins

The Neve 88RS Channel Strip Collection is comprised of the UAD Neve 88RS and UAD Neve 88RS Legacy plug-ins. The plug-ins are based on a "golden unit" channel strip from an original Neve 88RS large-format console, including the original P&G output attenuating fader.

Neve 88RS The UAD Neve 88RS Channel Strip provides the *only* authentic, end-to-end circuit model of the 88RS channel strip. An extremely detailed model was made of the 88RS, starting with the input transformer, and real physical impedance switching when used with Apollo's Unison technology.

The four-band, active EQ's filter interactions and internal amp clipping behaviors are also modeled along with the cut filters. The plugin also captures the non-linear behaviors of the 88RS's post-fader output amplifier, the output transformer, and much more.

The Neve 88RS uses an internal upsampling technique to achieve sonic design goals. The upsampling results in a slightly larger latency than non-upsampled UAD plug-ins (between 55 and 88 samples, depending on the plug-in and sample rate). These additional samples are automatically compensated by modern host DAWs. See Upsampled Plug-Ins for more information.

Note: The Neve 88RS Legacy does not use upsampling.

Neve 88RSWhen physical amplification is not required or circuit non-linearities are not
desirable (when a very clean sound is wanted), the UAD Neve 88RS Legacy
channel strip provides a spot-on linear emulation of the 88RS.

Because the Neve 88RS Legacy does not include nonlinearities of the EQ or dynamics, nor modeling of the input and output stages, it uses significantly less UAD DSP resources than the newer Neve 88RS.

Unison™ Integration

The Neve 88RS features Unison technology for integration with the mic preamp hardware in Universal Audio's Apollo audio interfaces. With Unison, Apollo's ultra-transparent mic preamps inherit all of the unique sonics, input characteristics, and features of the Neve 88RS hardware preamp.

Note: Unison is active only when the Neve 88RS is inserted in the dedicated Unison insert within Apollo's Console application. For complete Unison details, see the Apollo Software Manual.

Realistic Tandem Control

Unison facilitates seamless interactive control of Neve 88RS plug-in settings using Apollo's digitally-controlled panel hardware and/or the plug-in interface. All equivalent preamp controls (gain, pad, polarity) are mirrored and bidirectional. The preamp controls respond to adjustments with precisely the same interplay behavior as the Neve 88RS hardware, including gain levels and clipping points.

Hardware Input Impedance

All Apollo mic preamps feature variable input impedance in analog hardware that can be physically changed by Unison plug-ins for physical, microphone-to-preamp resistive interaction. This impedance switching enables Apollo's preamps to physically match the emulated unit's input impedance, which can significantly impact the sound of a microphone. Because the electrical loading occurs on input, prior to A/D conversion, the realism is faithful to the original target hardware preamp.

Tactile Gain Staging

Apollo's front panel preamp knob can independently adjust the gain and level parameters available within the Unison plug-in via Gain Stage Mode. The gain stage being adjusted can be remotely switched via Apollo, so the gain levels and their associated colorations can be tuned from the hardware knob for precise physical tactile control, all without using the Unison plug-in's software interface.

Note: Unison technology is not available with Neve 88RS Legacy.

Artist Presets The Neve 88RS includes artist presets from prominent Neve 88RS users. The artist presets are in the internal factory bank and are accessed via the host application's preset menu. The artist presets are also placed by the UAD installer so they can be used within Apollo's Console application. The presets can be loaded using the Settings menu in the UAD Toolbar (see "Using UAD Powered Plug-Ins" in the UAD System Manual).

Operational Overview

With a rich palette of modern sound-sculpting tools, the Neve 88RS Channel Strip captures the essence of Neve's flagship console. The console controls are comprised of the mic/line preamp, 12 dB per octave high and low cut filters, four-band EQ, and dynamics processors for limiting, compression, gate, and expansion.

The middle EQ bands are fully parametric, while the flexible high and low bands provide two fixed-Q types and the ability to switch to shelving EQ.

The limiter/compressor VCA provides a 0.01s to 3s release, auto release, and a continuously variable ratio control with a fixed fast or slow attack time. The gate/expander provides 0.01 to 3s release times, fast or slow attack times plus threshold, range, and hysteresis controls for tailoring the gate or expansion processors to the perfect response for any source signals.

With the sidechain EQ (SC-EQ) feature, frequency-dependent dynamics processing is available for tasks such as de-essing.

ModulesThe Neve 88RS and Neve 88RS Legacy controls are grouped within modules.Both plug-ins contain dynamics, EQ, and cut filter modules. The Neve 88RSincludes a preamp module that is unavailable with Neve 88RS Legacy.

Signal Flow The output of the cut filters is routed to the input of the dynamics module or the EQ module, depending on the state of the Pre-Dyn switch, as shown in Figure 92. By default, dynamics is before EQ. Engaging Pre-Dyn routes EQ before dynamics.

Figure 92. Simplified signal flow within UAD Neve 88RS

Neve 88RS Controls

The module controls for the Neve 88RS and Neve 88RS Legacy plug-ins are essentially identical. Any control differences are individually noted.

Preamp Module

The Neve 88RS contains complete modeling of the original console's preamplifier module. Refer to Figure 93 for control descriptions in this section.

Note: The Neve 88RS Legacy does not include the preamp module.

Figure 93. The Neve 88RS preamp elements

Input Select The input select switches determine which input gain knob (LINE or MIC) is active. The input is selected when the indicator LED on the LINE or MIC switch is illuminated.

Like the hardware, the Neve 88RS plug-in easily facilitates sending line level signals through the "virtual" mic input, which allows creative use of distortion to color signals. This is the equivalent of routing a line level signal into a mic level input, so a large jump in gain is expected.

Note: Use caution when switching to Mic from Line, as output levels can increase significantly (as they would with any hardware preamp).

	When Neve 88RS is used in a Unison insert within Apollo's Console application, software and hardware control of Input Select is mirrored. Input Select can be changed within the plug-in interface, with Console's MIC/LINE buttons, or with Apollo's hardware buttons (MIC/LINE on Apollo, or INPUT on Apollo Twin).
	Note: If the Hi-Z input is connected with Unison, the MIC input is automatically selected.
Line Gain	Line Gain has a range of -15 dB to +15 dB. To increase the line input gain, rotate the knob clockwise.
	Tip: Click the "O" text label to return the control to 0 dB.
Mic Gain	Mic Gain has a range of +20 dB to +70 dB. To increase the mic input gain, rotate the knob clockwise.
	Tip: Click the "MIC" text label to return the control to 40 dB.
	Unison Impedance
	When Neve 88RS is used in a Unison insert within Apollo's Console application, the hardware input impedance of the Apollo mic preamp is switched to match the value in the plug-in for physical, microphone-to-preamp resistive interaction.
	Matching the microphone to the closest impedance value is generally recom- mended, but this parameter can be used creatively and will not harm equip- ment connected to the Apollo mic preamp.
Overload	The Overload LED indicates when signal clipping is occurring at the modeled preamp input stage. The indicator remains illuminated for one second after a clip is detected.
	Note: Overload does not indicate A/D converter clipping when the plug-in is used in a Unison insert within Apollo's Console application.
Ø (Polarity)	The Ø (polarity) switch inverts the polarity of the input signal. When the switch's red indicator LED is illuminated, the input polarity is inverted. Leave the switch disengaged (LED off) for normal polarity.

When the plug-in is used in a Unison insert within Apollo's Console application, software and hardware control of polarity is mirrored. Polarity can be inverted within the plug-in interface, with Console's polarity button, or with Apollo's hardware polarity button.

Control Location

With Neve 88RS, the Polarity switch is located within the preamp module, below the line gain knob. With Neve 88RS Legacy, the switch is located within the global controls section.

-20 (Pad) When the -20 switch is enabled, the signal level at the mic input is attenuated (lowered) by -20 dB. The pad is active when the indicator LED on the -20 switch is illuminated.

Pad can be used to reduce signal levels when undesirable overload distortion is present at low preamp gain levels.

Note: Pad is not available for line input, or when used with Apollo's Hi-Z input in Unison mode. In these cases, the control cannot be switched.

When Neve 88RS is used in a Unison insert within Apollo's Console application, software and hardware control of the pad is mirrored. Pad can be switched with the -20 button in the plug-in interface, with Console's PAD button, or with Apollo's hardware PAD button.

Cut Filters Module

Neve 88RS offers two cut filters, one each for low and high frequencies. The slope of the cut filters is 12 dB per octave. Each cut filter has two controls: Enable and Frequency.

Low Cut with Unison

When toggling the filter enable state with the hardware button on Apollo, the last set frequency value is toggled.

Controls Location

With Neve 88RS, the cut filters are located between the preamp and dynamics modules in the left column of the plug-in. With Neve 88RS Legacy, the filters are located above the global controls section.

Refer to Figure 94 for control descriptions in this section.

Figure 94. Neve 88RS Cut Filters

Cut Enable	Each cut filter is active when its dedicated enable switch is engaged. The appearance of these switches vary according to the plug-in, as detailed below.
	Note: UAD DSP load is not reduced when the cut filters are disabled.
	Neve 88RS
	To activate a cut filter, click the "pull" label text or the red indicator LED just below the Cut Frequency control. The cut filter is active when its red indicator is illuminated.
	Neve 88RS Legacy
	To activate a cut filter, click the enable switch just below the Cut Frequency control. The cut filter is active when its red indicator is illuminated.
Cut Frequency	The frequency knobs determine the cutoff frequency for the cut filter.
	High Cut
	The available range is 7.5 kHz to 18 kHz for the high cut filter (lighter blue control).
	Low Cut
	The available range is 31.5 Hz to 315 Hz for the low cut filter (darker blue control).

Dynamics Module

The dynamics section consists of a gate/expander and a limiter/compressor. The controls for each of these two dynamics processors are arranged in vertical columns, with the gate/expander controls in the left column, and the limiter/compressor controls in the right column. Both processors can be individually activated or disabled.

Refer to Figure 95 for control descriptions in this section.

Figure 95. The Neve 88RS dynamic processing elements

The settings of the gate do not affect operation of the compressor, and vice versa. The same sidechain signal (EQ'd or not, depending on the SC-EQ switch) is sent to both the gate and compressor. The gains for both the gate and compressor are computed based on that same signal, then both the gate and compressor gains are applied in the same place, by a single gain-reduction VCA (see Figure 92).

The activity of the dynamics processor are displayed in the Meters.

Sidechain Link When Neve 88RS is used in a stereo-in/stereo-out configuration and LINK is enabled (when the LINK switch LED is illuminated), it causes the two channels of the compressor to compress in equal amounts.

Linking the sidechains simply means that the instantaneous amount of compression for the two channels will always be the same, thereby preventing leftright image shifting at the output.

Note: This control is unavailable on the Neve 88RS Legacy. The Neve 88RS Legacy sidechain is always linked when used in a stereo or mono-in/stereo-out configuration.

Sidechain EQ (SC-EQ) This control enables the Neve 88RS sidechain function. When sidechain is active, signal output from the EQ module is removed from the audio path and is instead routed to control the dynamics module. Sidechain EQ is active when the button's red indicator LED is illuminated.

Note: The EQ module and at least one dynamics module must be active in conjunction with SC-EQ for the sidechain to function (see "EQ Enable (EQ)" on page 328). SC-EQ overrides P-DYN if both functions are enabled.

Sidechaining is typically used for de-essing and similar frequency-conscious techniques. To listen to the sidechain key, simply disengage SC-EQ to hear the EQ'd signal.

Note: The sidechain dynamics/EQ implementations are true stereo when used in a stereo-in/stereo-out configuration.

Control Location

With Neve 88RS, the Sidechain EQ switch is located within the dynamics module, at the lower left of the plug-in window. With Neve 88RS Legacy, the switch is located within the global controls section.

Gate/Expander

The gate/expander module operates in either gate or expansion mode. In gate mode, signals below the threshold are attenuated by the range (RGE) amount (Figure 96), and hysteresis is available (Figure 97).

Expansion mode is enabled by rotating the hysteresis (HYST) control fully counter-clockwise (or clicking the EXP label). In expansion mode, the gate applies downwards expansion at a fixed 1:2 ratio, with the amount of gain reduction determined by the range control. Two attack speeds and a continuously variable release time are available in both modes.

Figure 96. Gate/Expander diagrams

Gate/Exp
Enable (G/E)This button activates the gate/expander module. The module is active when
the green indicator LED is illuminated.

This button can be used to compare the gate/expander settings to that of the original signal, or to bypass the module altogether. UAD DSP load is reduced when this module is inactive (unless UAD-2 DSP LoadLock is enabled).

Gate/Exp Hysteresis (HYST) The Hysteresis knob sets the difference in threshold for signals that are either rising or falling in level. Signals that are rising in level are passed when the level reaches the threshold value plus the hysteresis value. Signals that are falling in level are not passed at the lower threshold level. Up to 25 dB of hysteresis is available. See Figure 97. Hysteresis makes the gate less susceptible to "stuttering" by making the threshold value dependent upon whether the gate is off or on. Raising the threshold for rising signal levels prevents noise from activating the gate, while allowing a lower threshold for falling levels. This prevents reverb tails from being prematurely gated. For example, if the threshold is set at -50 and the hysteresis is set at 10, the level would have to rise above -40 dB before the signals pass, and the gate would remain open until the level falls below -50 dB.

This control also activates expander mode. Rotating Hysteresis fully counterclockwise disables the gate and activates the 1:2 downward expander.

Note: Expander mode can also be activated by clicking the EXP label text near the knob. When EXP is clicked again, the knob returns to the previous value in gate mode.

Gate/Exp Threshold (THR) Threshold defines the input level at which expansion or gating occurs. Any signals below this level are processed. Signals above the threshold are unaffected.

The available range is -25 dB to +15 dB. A range of -25 dB to -65 dB is available when the Gate/Exp Threshold -40 dB switch is engaged.

	In typical use it's best to set the threshold value to just above the noise floor of the desired signal (so the noise doesn't pass when the desired signal is not present), but below the desired signal level (so the signal passes when present).
Gate/Exp Threshold -40 dB	The -40 dB switch increases the sensitivity of the gate and expander by low- ering the range of the available threshold values. When -40 dB mode is ac- tive, the threshold range is -25 dB to -65 dB. When -40 is inactive, the thresh- old range is -25 dB to +15 dB.
	To activate -40 dB mode, click the "pull -40" label text or the red indicator LED just below the Threshold control40 dB mode is active when the red indicator is illuminated.
Gate/Exp Range (RGE)	Range (RGE) controls the difference in gain between the gated/expanded and non-gated/expanded signal. Higher values increase the attenuation of signals below the threshold. When set to zero, no gating or expansion oc- curs. The available range is 0 dB to -60 dB.
Gate/Exp Fast	The Fast mode switch defines the gate/expander attack time, which is the du- ration between the input signal reaching the threshold and processing being applied. Two times are available: 500 microseconds (when Fast is off) and 50 microseconds (when Fast is active).
	To activate Fast mode, click the "pull FAST" label text or the red indicator LED just below the Range (RGE) control. Fast mode is active when the red indicator is illuminated.
Gate/Exp Release (REL)	Release sets the amount of time it takes for processing to disengage once the input signal drops below the threshold level. The available range is 10 milli-seconds to 3 seconds.
	Slower release times can smooth the transition that occurs when the signal dips below the threshold, which is especially useful for material with frequent peaks.
	Note: Fast release times are typically only suitable for certain types of percussion and other instruments with very fast decays. Using fast settings on other sources may produce undesirable results.
Gate/Exp Meter	The G/E meter (see Meters) displays the amount of gain attenuation (down- ward expansion) occurring in the gate/expander module.

Limiter/Compressor

The limiter/compressor module (Figure 95) offers a continuously variable ratio between 1:1 (no compression) and infinity:1 (limiting). Signals above the threshold are attenuated according to the ratio (RAT) value. Two attack speeds and continuously variable release times are available, along with a pleasing automatic triple time-constant program-dependent release mode (auto mode has a three-stage release). A makeup gain control and a hard/soft knee setting are also available in the module.

From the AMS-Neve 88RS User Manual: "Anti pumping and breathing circuitry allows the unit to operate on the source musically whilst retaining absolute control over the dynamic range."

The 88RS compressor has another nifty property: Two thresholds. When the signal falls below the threshold, the compressor is releasing. But, if the signal falls below a second (non-adjustable) threshold, which is roughly 40 dB below the adjustable threshold value, then the release slows down drastically. This acts as a "silence detector." The concept is that if there is a quiet signal, then the compressor should release to reduce the dynamic range. But if there is a sudden onset of silence, it is likely that, when the signal returns, it will be at about the same level as the region before the silence. So in that case, the compressor doesn't release quickly.

An example: When compressing a snare track with a standard compressor, if the snare hits are sparse, the compressor will release between each hit, so that each hit has a squashed sound. With the 88R compressor, distortion will be reduced, because the compressor will not come out of compression as much between the snare hits. The compressor will still release somewhat during the snare hits, however.

L/C Enable (L/C) This button activates the limiter/compressor module. The module is active when the green indicator LED is illuminated.

This button can be used to compare the limiter/compressor settings to that of the original signal, or to bypass the module altogether. UAD DSP load is reduced when this module is inactive (unless UAD-2 DSP LoadLock is enabled).

L/C Gain The Gain control adjusts the output level of the limiter/compressor module. The available range is 0 dB to 30 dB.

	Generally speaking, adjust this makeup gain control after the desired amount of processing is achieved with the Threshold control. The Gain control does not affect the amount of processing.
L/C Hard Knee (HN)	Normally, the limiter and compressor operate with soft knee characteristics. This switch gives the limiter and compressor a hard knee instead.
	To activate Hard Knee mode, click the "pull HN" label text or the red indica- tor LED just below the Gain control. Hard Knee mode is active when the red indicator is illuminated.
L/C Threshold	Threshold defines the input level at which limiting or compression begins. Sig- nals that exceed this level are processed. Signals below the threshold are un- affected.
	The available range is +20 dB to -10 dB. A range of 0 dB to -30 dB is available when the L/C Threshold -20 dB switch is engaged.
	Tip: As threshold is increased and more processing occurs, the output level is typically reduced. Adjust the L/C Gain control to increase the output of the module to compensate if desired.
L/C Threshold -20 dB	The -20 dB switch increases the sensitivity of the limiter/compressor by low- ering the range of the available threshold values. When -20 dB mode is ac- tive, the threshold range is 0 dB to -30 dB. When -20 is inactive, the threshold range is +20 dB to -10 dB.
	To activate -20 dB mode, click the "pull -20" label text or the red indicator LED just below the Threshold control20 dB mode is active when the red indicator is illuminated.
L/C Ratio (RAT)	Ratio defines the amount of gain reduction to be processed by the module. For example, a value of 2 (expressed as a 2:1 ratio) reduces the signal by half, with an input signal of 20 dB being reduced to 10 dB.
	A value of 1 yields no gain reduction. When the control is at maximum ("lim"), the ratio is effectively infinity to one, yielding the limiting effect. The available range is 1 to infinity.
L/C Fast	The Fast mode switch defines the attack time (the duration between the input signal reaching the threshold and processing being applied) of the limiter and compressor.

Attack time is program dependent. Two ranges are available: 3 milliseconds to 7 milliseconds (Fast off) and 1 millisecond to 7 milliseconds (Fast active).

To activate Fast mode, click the "pull FAST" label text or the red indicator LED just below the Ratio (RAT) control. Fast mode is active when the red indicator is illuminated.

L/C Release Release sets the amount of time it takes for processing to cease once the input signal drops below the threshold level. The available range is 10 milliseconds to 3 seconds, and automatic.

Automatic triple time-constant program dependent release time is activated by turning the release control fully clockwise (to 3s) or by clicking the "AUTO" label text.

Slower release times can smooth the transition that occurs when the signal dips below the threshold, which is especially useful for material with frequent peaks. However, if the release is too long, compression for sections of audio with loud signals may extend to sections of audio with lower signals.

Note: Fast release times are typically only suitable for certain types of percussion and other instruments with very fast decays. Using fast settings on other sources may produce undesirable results.

L/C Meter The L/C meter (see Meters) displays the amount of gain attenuation occurring in the limiter/compressor module.
EQ Module

From the AMS-Neve 88RS manual:

"The unique sound of AMS-Neve EQ is the result of years of research and extensive studio experience."

The Neve 88RS "Formant Spectrum EQ" (AMS-Neve's descriptor) is divided into four frequency bands (Figure 98): High Frequency (HF), High Midrange Frequency (HMF), Low Midrange Frequency (LMF), and Low Frequency (LF). The high and low bands can be switched into shelving and/or High-Q modes. The two midrange bands are fully parametric. The EQ module can be disabled altogether.

When the high frequency (HF) and/or low frequency (LF) band is in shelf mode, the band gain affects the band frequency. As gain is increased, the shelf frequency more closely matches the knob value. As gain is reduced however, the low shelving frequency moves higher, and the high shelving frequency moves lower.

With the Neve 88RS EQ, the Q value and range is dependent on the gain setting of the band. With any non-zero gain setting, the Q will be calculated in real-time for that band. But if the band gain is zero, Q will always display zero.

Pre-Dynamics (P-DYN) By default, the audio signal is routed from the dynamics module into the EQ module (the EQ is post-dynamics). The signal can be routed so the EQ is predynamics using the P-DYN switch. When the switch is enabled (when the button's red indicator LED is illuminated), the EQ module precedes the dynamics module (Figure 92).

Note: Pre-dynamics can only be engaged if the EQ module and at least one dynamics module is active.

Control Location

With Neve 88RS, the Pre-Dynamics switch is located within the EQ module, near the high frequency controls. With Neve 88RS Legacy, the switch is located within the global controls section.

88RS EQ Band The grouping of band controls within the EQ module is shown in Figure 98. Layout

Figure 98. Neve 88RS EQ controls layout

EQ Controls

Refer to Figure 99 for control descriptions in this section.

Figure 99. Neve 88RS EQ controls

EQ Enable (EQ) This button activates the equalizer module. The module is active when the green indicator is illuminated.

This button can be used to compare the equalized signal to the original signal or bypass the EQ altogether. UAD DSP load is reduced when this module is inactive (unless UAD-2 DSP LoadLock is enabled).

High Band HF Freq

This parameter determines the HF band center frequency to be boosted or attenuated by the band Gain setting. The available range is 1.5 kHz to 18 kHz.

HF Gain

This control determines the amount by which the frequency setting for the HF band is boosted or attenuated. The available range is ± 20 dB.

Tip: Click the "0" text label to return the control to 0 dB.

HF Hi-Q Enable

The filter slope of the HF band can be changed with this control. When Hi-Q is off, the Q is 0.7. When Hi-Q is active, the Q is 2. Higher Q values mean the peak (or trough) has steeper slopes.

Hi-Q is active when the yellow indicator LED is illuminated. Hi-Q is off by default.

Note: Hi-Q has no effect when the band is in shelf mode.

HF Shelf Enable

The HF band can be switched from bell mode to shelving mode by clicking the shelf enable button. Shelf mode is active when the yellow indicator LED is illuminated. Shelf is off by default.

High Mid Band HMF Freq

This control determines the HMF band center frequency to be boosted or attenuated by the HMF Gain setting. The available range is 800 Hz to 9 kHz.

HMF Gain

This control determines the amount by which the frequency setting for the HMF band is boosted or attenuated. The available range is ± 20 dB.

Tip: Click the "0" text label to return the control to 0 dB.

HMF Q

The Q (bandwidth) control defines the proportion of frequencies surrounding the HMF band center frequency to be affected by the band gain control. The filter slopes get steeper (narrower) as the control is rotated clockwise. The available range is 0.4 to 10.

Low Mid Band LMF Freq

This control determines the LMF band center frequency to be boosted or attenuated by the LMF Gain setting. The available range is 120 Hz to 2 kHz.

LMF Gain

This control determines the amount by which the frequency setting for the LMF band is boosted or attenuated. The available range is ± 20 dB.

Tip: Click the "0" text label to return the control to 0 dB.

LMF Q

The Q (bandwidth) control defines the proportion of frequencies surrounding the LMF band center frequency to be affected by the band gain control. The filter slopes get steeper (narrower) as the control is rotated clockwise. The available range is 0.4 to 10.

Low Band LF Freq

This parameter determines the LF band center frequency to be boosted or attenuated by the band Gain setting. The available range is 33 Hz to 440 kHz.

LF Gain

This control determines the amount by which the frequency setting for the LF band is boosted or attenuated. The available range is ± 20 dB.

Tip: Click the "0" text label to return the control to 0 dB.

LF Shelf Enable

The LF band can be switched from bell mode to shelving mode by clicking the shelf enable button. Shelf mode is active when the button is gray and the yellow indicator illuminates. Shelf is off by default.

LF Hi-Q Enable

The filter slope of the LF band can be switched with this control. When Hi-Q is off, the Q is 0.7. When Hi-Q is active, the Q is 2. Higher Q values mean the peak/trough has steeper slopes.

Hi-Q is active when the button is gray and the yellow indicator illuminates. Hi-Q is off by default.

Note: Hi-Q has no effect when the band is in shelf mode.

Global Controls

Meters	G/E				
	Displays the amount of dynamics processing occurring in the gate/expand module.				
	L/C $12 \\ 10 \\ 5 \\ -20 \\ 12 \\ 10 \\ 5 \\ -20 \\ $				
	Displays the amount of dynamics processing occurring in the limit/compress module.				
	VU				
	Displays the signal level at the output stage of the plug-in.				
	Note: Neve 88RS Legacy does not have VU meter.				
Level Fader	Level boosts or attenuates the signal level at the final output amplifier stage of the channel strip. The circuitry of an original Neve88RS console fader was modeled for this control; higher levels can clip the output just as the original hardware can.				
	The available range is from - ∞ dB (off) to +10 dB. Unity gain is at the zero position.				
	Tip: Click the "0" text labels to return Level to 0 dB.				
Output	Output adjusts the signal level at the output of the plug-in without effecting the sonic character of the signal. The available range is ±20 dB.				
	This control, which does not exist on the original hardware, facilitates the abil- ity to maximize color of the overall signal. For example, Gain and Level can be cranked for more distortion, while lowering Output to normalize levels.				

The Power switch determines whether the plug-in is active. It can be used to compare the processed settings to the original signal and/or to bypass the plug-in to reduce the UAD DSP load (load is not reduced if UAD-2 DSP LoadLock is enabled).

Toggle the switch to change the Power state; the switch is illuminated in red when the plug-in is active.

Note: Click-hold the power switch then drag it like a slider to quickly compare the enabled/disabled state.

CHAPTER 32

Ocean Way Studios

Dynamic Room Modeling

Welcome to Ocean Way Studios — the World's First Dynamic Room Modeling Plug-In

Developed by Universal Audio and Allen Sides, the Ocean Way Studios plug-in re-writes the book on what's possible with acoustic space emulation. By combining elements of room, microphone and source modeling, Ocean Way Studios moves far beyond standard impulse response players and reverbs — giving you an authentic dynamic replication of one of the world's most famous recording studios.

Ocean Way Studios allows you to virtually book unlimited time at Ocean Way Recording in Hollywood, California (formerly a part of United/Western Recorders). This plug-in provides everything you need to help make your music sound as if it were recorded in the beautifully balanced, performance-inspiring rooms that were designed and built by modern recording pioneer and Universal Audio founder M.T. "Bill" Putnam.

Additionally, the Ocean Way plug-in grants virtual access to \$250,000 worth of hand-picked, vintage microphones from Allen Sides' personal collection – one of the largest in the world – all of which are capable of being moved and changed dynamically within the studio spaces as three separate stereo microphone pairs.

UA's proprietary Dynamic Room Modeling combines DSP and exclusive measurement techniques to reinvent room ambience processing. The end result is an uncanny recreation of Ocean Way's iconic studio rooms A and B. By nature of its specialization, the Ocean Way Studios plug-in invites its users to explore the entire space of these never-before-available temples of legendary sound.

Allen Sides' microphone setups are the centerpiece of Ocean Way Studios. They capture the ideal microphone selections and placements for each room and source type, and create Ocean Way Studios' fundamental sound. Mr. Sides' eight expertly chosen positions are featured per studio as discrete instrument or vocal source selections; each is designed to recreate its inherent dispersion patterns. This enables users to recreate the same set-ups used to record some of the biggest acts of all time — including Michael Jackson, Madonna, U2, Ray Charles, Radiohead, Beck, Tom Petty, The Rolling Stones, and many, many more.

Even the unique consoles in each room have been incorporated into the overall sound — the Ocean Way Recording-modified Focusrite ISA 110 console in Studio A, and the famous custom-modified Putnam/Dalcon console in Studio B.

Ocean Way Studios Screenshot

Figure 100. The UAD Ocean Way Studios plug-in window

What Is Ocean Way Studios?

Ocean Way Studios is a dynamically adjustable room emulator for adding the ambience of Ocean Way Recording's acclaimed studios A or B to audio signals.

Figure 101. Interior photos of Room A (left) and Room B (right) at Ocean Way Recording

Ocean Way Studios offers two modes of operation. It can be used as a traditional reverb using send/return paths mixed with dry signals, or as a "Re-Mic" processor when full immersion of the original source audio within Ocean Way's studio spaces is desired.

Re-Mic mode is by nature "fully wet" and includes the impulse response's "direct" signal. Re-Mic can be used to entirely replace previous rooms and microphones, or create new complimentary room sounds.

- Allen Sides Ocean Way Studios was collaboratively developed under the creative direction of renowned producer/engineer Allen Sides. As the owner/operator of Ocean Way Recording for more than 30 years (see "The History of Ocean Way Recording" on page 359), his knowledge of how to record various sources within these studios is integral to the high quality results that can be achieved with Ocean Way Studios.
- **Microphones** Allen Sides is not only known for his audio engineering expertise, but also for his collection of prized microphones. The specific microphones that were used to develop Ocean Way Studios, and their placement positions on a variety of sources, were selected by Mr. Sides himself.

Hybrid Technology Ocean Way Studios is not a general impulse response ("IR") convolution reverb nor a typical algorithmic reverb. Instead, Ocean Way Studios utilizes breakthrough hybrid technologies, combining expertly sampled impulse responses with advanced algorithmic DSP techniques.

Concise Modeling Ocean Way Studios focuses on a limited set of studio spaces and exhaustively models numerous room positions, microphones, and sound source dispersion patterns — which all combine to provide the ultimate in acoustic realism. Ocean Way Studios is sonically superior in terms of overall model accuracy and dynamic customization.

Presets The factory presets are of particular importance with the Ocean Way Studios plug-in, because they are designed by Allen Sides and they capture his ideal microphone selections and placement positions for each studio and source. 32 presets are available in the internal factory bank, providing optimum control settings in both Re-Mic and Reverb modes. 10 additional presets that use the guitar cabinets as source can be accessed via the UAD Toolbar.

Choosing presets differs from simply choosing different Studio, Source, and Microphone selections. Because with Ocean Way Studios it's possible to select a variety of microphones and place the microphones in positions that don't sound optimum (just like in the physical realm), the presets provide excellent starting points for customizations and an easy way to quickly return to a great sound.

The factory presets have only one microphone pair enabled to ensure there are no undesirable phase interactions. Of course, more than one microphone pair can be used for sonic variety and/or to enable creative applications. "Phase Considerations" on page 344 for related information.

Note: Switching through presets is not instantaneous and sonic artifacts can occur while the presets are loading. See "Load Time" on page 346 for related information.

Operational Overviews

Overviews of important underlying concepts are presented below. For details about how to operate the specific controls, see "Ocean Way Studios Controls" beginning on page 348.

Modes Overview

Ocean Way Studios offers two modes of operation: Re-Mic and Reverb. These modes process signals in fundamentally different ways.

Recorded Sound Components Whenever a sound source is recorded in a naturally reverberant space, there are three primary sound components (Figure 102) that are captured by the microphone:

- **1.** The direct signal. This is the sound path that travels directly between the source and the microphone, without any reflected sounds from the walls, floor, ceiling, and objects.
- 2. The early reflections. These are the still-distinct individual reflections that are reflected off the walls, floor, ceiling, and objects before reaching the microphone.
- **3.** The late field (aka reverb tail or ambience). This is the indistinct "wash" that decays over time, comprised of all reflections in the room. The tail is usually considered the main component of reverb.

Figure 102. The main signal components in an acoustically recorded sound

It's important to notice that the recorded direct signal component (#1 on previous page) is different than pre-existing dry (unprocessed) acoustic recordings in a DAW. This is because within a DAW, the dry audio was already recorded – so it already contains the direct signal component (along with all the other components) that was captured by the microphone originally used. This distinction is fundamental to the Re-Mic process.

Re-Mic mode is a tool for "replacing" the original dry audio signal.

Re-Mic Processing

When Ocean Way Studios is in Re-Mic mode, the original dry signal is not mixed back in with the wet processed signal. Instead, the dry signal is processed to sound as if it were recorded inside the studio space itself, by emulating the direct signal component. This processed source signal thus inherits the sonic characteristics of the studio acoustics, source dispersion patterns, and microphones with more accuracy and realism than is possible with reverb processing.

The concept is similar to that of guitar "re-amping" whereby previously recorded guitar tracks are routed out of the DAW, into a guitar amplifier, then re-recorded using a microphone to replace the original guitar track with a new track that inherits the sonic characteristics of the amp. This technique is also used in studios to great effect by "re-micing" any pre-existing audio to inherit the sonic characteristics of the recording room.

In the same way, with Ocean Way Studios, any track or bus can be routed into the plug-in to "re-record" the original source so it inherits the sonic characteristics of the Ocean Way studio acoustics, source dispersion patterns, and microphones.

Reverb ProcessingIn artificial reverb processors, the direct signal component is not actually part of the processed signal. Instead, the original dry signal is simply mixed back in with the reverb ambience (the wet signal). Although great results can be obtained with this method, it is only an approximation of what really happens in the physical realm.

When Ocean Way Studios is in Reverb mode, the plug-in behaves like most artificial reverb processors. The direct signal component is not in the processed signal. Instead, the original dry signal is mixed back in with the wet reverb ambience.

For additional details about Reverb and Re-Mic modes, see "Using Ocean Way Studios" on page 342.

Microphones Overview

In addition to the studio room acoustics, the microphones used in the development of Ocean Way Studios are a significant contributor to the tonality and fidelity of the plug-in.

Microphone Selections Ocean Way Studios contains 11 different microphone pairs. Additionally, some of these microphone pairs are available with cardioid and omnidirectional polar frequency response patterns. The microphones that are available,

along with their descriptions, are listed in Table 24 below.

Microphone*	Description
C12	Allen's incredibly clear and present C12s, these large diaphragm tube condenser mics use a dual backplate design providing great off-axis frequency response.
C12A	The next-generation, multi-pattern tube condenser mic provides excellent close mic response and consistent low frequency response at further distances.
M50	Noted for its far distance placement consistency, the response of this medium diaphragm omnidirectional mic becomes more cardioid above 800 Hz. Allen Sides' favorite microphone.
KM54	The studio standard KM54 is a nickel capsule, medium diaphragm, pressure gradient cardioid condenser tube mic, providing maximum on-axis sensitivity.
MKH20	The secret weapon omni MKH20 provides rise in directionality at high frequencies. OWR B Far Strings, Horns and Vocal Group has Allen placing the MHK20s at the walls. Distance is unavailable when this mic is used for the OWR B Far selection.
U67	A multi-pattern dual diaphragm tube condenser mic with a distinct sonic signature. This "best of the best" set was picked by Allen from his collection.
U47	One of the most recognizable mics in recording, this multi-pattern tube condenser is prized for its amazing realism and clarity.
KU3A	Only about a hundred of these amazing cardioid ribbon mics were ever made, providing an "impressionistic" sound useful within a multi-pair setup.
44	The iconic American figure-8 ribbon velocity mic used for broadcast, studio, and live sound is noted for its strong off-axis rejection and smooth tone.
SM57	No mic locker is complete without this cardioid pattern, high rejection dynamic studio workhorse, which features a familiar bass roll-off and mid-range presence.
4006	A razor-flat small diaphragm omni reference grade mic found in OWR B's loft as a permanent installation. Distance is unavailable when this mic is used for Far selection.

*Microphone names are all trademarks of their respective owners, which are in no way associated or affiliated with Universal Audio or Ocean Way Recording. These microphone names, descriptions and images are provided for the sole purpose of identifying the specific microphones studied during Universal Audio's sound model development and to describe certain microphone sound qualities and performance characteristics. Ocean Way Studios is a trademark used under license by Ocean Way Recording Inc.

Polar Patterns All microphone selections are denoted with O, C, or 8 after their name. Microphones with "O" after the name indicates the polar frequency response pattern of the mic is omnidirectional. Microphones with "C" after the name indicates the polar pattern of the mic is cardioid. Microphones with "8" after the name indicates the mic has a "figure 8" polar pattern.

In simplistic terms, omni microphones are equally sensitive to sound pressure levels from all directions, while cardioid microphones are more sensitive to sound from the front of the mic and less sensitive from the rear of the mic. Figure 8 microphones are equally sensitive at the front and rear of the mic, but less sensitive at the sides.

Near/Mid/Far Up to three microphones pairs (Near, Mid, Far) are available. Each microphone pair can be active simultaneously for creative sonic blending.

Independent Controls

Each microphone pair has its own set of controls that can be independently adjusted. The individual microphone controls are Selection, Distance, High Cut Filter, Low Cut Filter, Polarity Invert, Mute, Balance, and Level. For details about how to operate these controls, see "Mic Selection" on page 353.

Generally speaking, the closer a microphone pair is to the source, the less room ambience is captured by the microphones, so a Far microphone pair will tend to have more ambience (more "live") than a Near microphone pair.

Note: Just as in the physical realm, there can be signal phase interactions when using more than one microphone simultaneously. For details, see "Phase Considerations" on page 344.

Mic Positions The microphone placement positions within the studio rooms are specified by Allen Sides based on his expertise of which microphone positions produce great results for a given studio and source. Although these pre-defined microphone positions cannot be moved from side-to-side, they can be moved closer or farther with the Distance control.

Distance

The distance from the microphone pair to the source can be dynamically adjusted using the Distance control. Just as when recording with microphones in the physical realm, the mic-to-source distance can have a significant impact on the sound that is captured.

The room will sound tighter and more present the closer the mics are to the

source; conversely, the room gets "bigger" when the mics are farther away from the source. The Ocean Way Studios modeling includes the proximity gain that occurs in the physical realm; the signal can be notably louder as microphones are positioned closer to the source.

Stereo Separation

The separation between a stereo microphone pair varies depending on the microphone pair selected and its Distance setting. With most settings, the separation increases incrementally as the distance from the source increases.

Fixed Distance Microphones

When Studio is set to OWR B and Source is set to Strings, Horns, or Vocal Group, the 4006 and MKH20 selections for the Far microphone cannot be repositioned with the Distance control.

With the Far MKH20, this is a specialized setup whereby Mr. Sides chose to set the microphones near the walls for the best sound. With the Far 4006, this is because these mics are fixed installations in the studio loft (they cannot be adjusted in the real studio either).

Distance Delay (Aligned) Overview When recording a sound source with a microphone, there is an inherent delay between the source and the microphone. This delay is the time it takes for the sound waves to physically travel from the source to the mic (see Figure 103 on page 341). The farther the distance is from the source to the mic, the longer the delay time.

> When a microphone pair in Ocean Way Studios is set to "aligned" by clicking its Distance knob, this inherent mic delay is artificially removed so the sound source "reaches" the mic instantaneously. The setting is useful when the source audio signals need to remain time-aligned, or simply for its own physically-impossible sonic effect.

Removing this inherent delay can be especially useful in these scenarios:

- If a source is recorded with a distant room mic, it will play back later in relation to sources that are close-miced. Typically, this delay can be compensated in the DAW by manually shifting the track forward in time so it aligns with the other instruments. With Ocean Way Studios, removing the microphone delay will align the distant mics automatically.
- When the microphone pair is distant from the source, the additional microphone delay can be problematic for performers tracking in realtime while monitoring through the plug-in. Setting the microphone pairs to aligned reduces realtime latency.

Tip: The most realistic acoustic emulations are recreated when the distance delay is retained (aligned off). This is because the inherent source-to-mic delays provide subtle yet important auditory cues that our brains use to interpret the acoustic space.

Figure 103. Illustration of Distance Delay. When set to aligned, this "extra" time is eliminated.

Acoustic Balancing All rooms have frequency-dependent resonances that impact the loudness and sonic balances within the room. Furthermore, microphone selections and their placement within the room, as well as the audio source itself, all impact the relative levels and timbres that are captured in a recording.

Although the studios at Ocean Way are beautifully designed and tuned, they are naturally subject to the same acoustic principles. Because the plug-in accurately models the ingredient interdependencies, certain combinations of studios, sources, mic selections, and mic placements may cause the level balances to seem too quiet or too loud, or the balance may not be perfectly centered. Microphone Gain and Balance controls are provided to compensate for these imbalances, providing ample practical and creative flexibility to achieve the desired results.

Using Ocean Way Studios

For details about how to operate the specific controls, see "Ocean Way Studios Controls" beginning on page 348.

Best On Dry Sources Ocean Way Studios does not remove already-recorded ambience from existing audio signals. For optimum ambience control when using the plug-in, the source audio should be as dry as possible. However, Ocean Way Studios is very forgiving, and great results can be obtained even if the original source has existing ambience.

Tip: Using ambience reduction tools prior to processing with Ocean Way Studios can yield improved results with particularly ambient audio.

Which Mode? When to use Reverb mode

Use Reverb mode to add Ocean Way Studios ambience to existing sources just as you would with other reverb processors and methodologies. See "Reverb Processing" on page 337 for an overview of Reverb mode.

Figure 104 shows a traditional auxiliary effect bus send/return configuration in a DAW. In this example, Ocean Way Studios is inserted on the effects bus, the plug-in is in Reverb mode, and its Wet Solo control is enabled (100% wet). Individual reverb amounts are set with the send control for each individual channel, and the overall reverb amount is set with the bus return fader.

Tip: This configuration conserves UAD DSP resources when the same effect settings are desired for multiple channels (instead of using the plug-in on individual channels).

Figure 104. DAW signal routing in Reverb mode using a traditional effect send/return configuration.

When to use Re-Mic Mode

Use Re-Mic mode to "replace" existing audio with new audio that inherits the sonic characteristics of Ocean Way Studios. The original dry signal component is removed and completely immersed with Ocean Way room sound. See "Re-Mic Processing" on page 337 for an overview of Re-Mic mode.

Figure 105 shows how to configure the Re-mic workflow in a DAW. In this example, all the drums are routed to a submix bus instead of the main outputs. Ocean Way Studios is inserted on the submix bus return, and the plug-in is in Re-Mic mode. Note that the effect sends are *not* used in this configuration.

In Re-Mic mode, the Dry/Wet (mix) control is automatically fixed at 100% wet so the original dry signal does not stack or "phase" against the modeled direct component signal. Instead of an effect bus return (or mix control), the desired ambience is adjusted with the studio, source, and microphone selections, along with microphone placements and their relative levels.

Note: Because Re-Mic mode includes the direct signal path component in addition to the reverb components, the plug-in output is inherently louder in Re-Mic mode.

Figure 105. DAW signal routing with OWS in Re-Mic mode on a drum submix

Dual-Mode Example

Figure 106 shows how to use both Re-Mic and Reverb modes with two instances of the plug-in, combining the workflows of the two previous examples. The illustration combines a drum submix is being used for Re-Mic mode, while send/return routing is being used for guitar and vocals in Reverb mode.

Figure 106. DAW signal routing in a workflow with two Ocean Way Studios plug-in instances. One uses Re-Mic mode for the drum submix, and the other uses Reverb mode for the guitar and vocals.

Phase Considerations When recording in the physical world, it is possible for phase issues to manifest when more than one microphone is used on a source. The sonic characteristic of "phasing" (more accurately called comb filtering) results when frequencies that are being captured by more than one microphone are emphasized because they are summed (signals in phase) or de-emphasized because they are canceled (signals out of phase).

> Phase issues resulting from the use of multiple microphones can usually be diminished by simply adjusting the placement position(s) of the microphone(s), or switching its signal polarity.

Phasing with Ocean Way Studios

Phasing is intrinsic when recording with multiple microphones. Because Ocean Way Studios accurately models the acoustic space and the microphones within the space, it is possible for the plug-in to sound "phasey" due to phase issues if the controls are not properly set, especially in Re-Mic mode (phasing is generally not an issue in Reverb mode). Whenever more than one microphone pair is simultaneously enabled, careful attention should be paid to the Distance (position) and Polarity Invert parameters to avoid potential phase issues. Just as with moving microphones around and changing signal polarity when recording acoustically, changes to Distance and Polarity Invert can have a dramatic effect on the sound. Note that sometimes phasing can sound just fine, and can be useful for creative purposes.

Ocean Way Studios sounds amazing when set properly. If using more than one microphone and the plug-in doesn't seem to sound right, adjust the Distance and/or Polarity parameters on one (or more) of the microphones to taste until phasing is minimized.

Don't Include Original Dry Signal in Re-Mic Mode

Because Re-Mic mode includes the direct signal component, if the original dry signal is mixed with the processed signal when Ocean Way Studios is in Re-Mic mode, phasing is likely to occur in this configuration (for example, if the plug-in is in Re-Mic mode when used in a traditional effects bus send/re-turn configuration). For illustrations of proper DAW routing in Re-Mic mode, see Figure 105 on page 343 and Figure 106 on page 344.

Important: For the intended design results and to minimize phasing when Ocean Way Studios is in Re-Mic mode, exercise caution to ensure the original dry signal is not mixed with Ocean Way Studio's processed output.

Latency Ocean Way Studios is not an upsampled plug-in. However, due to its unique design requirements, Ocean Way Studios is subject to increased latency versus other UAD plug-ins.

The increased latency may be objectionable when tracking through Ocean Way Studios if the plug-in is in Re-Mic mode and/or on individual inserts in Reverb mode. This impediment also applies with Apollo when using the Console application for Realtime UAD Processing. The latency is typically not an issue when used in a typical effect send/return configuration in Reverb mode, nor during mixdown when latency is not a concern.

Therefore, when tracking live performances and the performer is monitoring through Ocean Way Studios, we generally recommend using it in Reverb mode using a typical effect send/return configuration where latency with time-based effects does not affect the monitored performance.

Note: Latency can be reduced further with "Distance Delay" on page 353.

The latency of Ocean Way Studios depends on the sample rate. The exact latency values are provided in Table 25.

Table 25. Latency in Ocean Way Studios

Sample Rate (kHz)	Latency (samples)	Latency (time)	Sample Rate (kHz)	Latency (samples)	Latency (time)
44.1	192	4.3 ms	96	688	7.1 ms
48	192	4.0 ms	176.4	1568	8.9 ms
88.1	688	7.8 ms	192	1568	8.2 ms

Note: As with all UAD plug-ins, the latency of Ocean Way Studios is automatically compensated by the DAW. See "Upsampled Plug-Ins" on page 563 for more information.

Load Time When certain Ocean Way Studios controls are modified (items in the two left-most columns in Table 26 on page 347), the impulse response engine is updated and/or microphone recalculations are performed by the plug-in.

These IR updates and recalculations are not instantaneous; there is a time lag before the new control values are heard. Additionally, sonic artifacts and/or host CPU increases can occur while these recalculations are performed if audio is currently being processed by the plug-in.

Because there are extensive interdependencies within the plug-in, the specific load time depends on the control(s) being modified. The "Load Progress LED" on page 352 is a status indicator that flashes during the reload.

Automation Limitations

The load time can be an impediment if the specific controls are modified with automation during a mix.

We recommend against changing specific controls with automation to avoid sonic artifacts and/or host CPU increases. If automation must be used on these controls, only snapshot automation should be used (instead of continuous automation), and only when the signal being processed is not audible (for example, between musical phrases). Parameter automation recommendations are listed in Table 26 on page 347.

Automation Not Recommended	Automation May Cause Zippering Artifacts*	Continuous Automation OK	
Studio: Select	Microphone: Distance	Mode (Re-Mic/Reverb)	
Source: Select	Microphone: Delay	Master: EQ Low Frequency	
Microphone: Select	Microphone: High Cut	Master: EQ Low Gain	
	Microphone: Low Cut	Master: EQ High Frequency	
	Microphone: Polarity	Master: EQ high Gain	
	Microphone: Mute	Master: L/R Swap	
	Microphone: Gain	Master: Mono Sum	
	Microphone: Gain	Master: Wet Solo	
	Master: Predelay	Master: Dry/Wet Mix	
		Master: Output Level	
		Master: Bypass	
*Snapshot (static) automation between audio passages is recommended if automation is used			

Table 26. Parameter Automation Recommendations

Ocean Way Studios Controls

Mode

Ocean Way Studios offers two modes of operation: Re-Mic and Reverb. Click a mode control to activate the mode. The button of the current mode is illuminated.

For details about the differences between these two modes, see "Modes Overview" on page 336.

Re-Mic

In Re-Mic mode, the dry signal path is eliminated and the audio is processed as if it was recorded inside Ocean Way Recording.

Important: For the intended design results and to minimize phasing when Ocean Way Studios is in Re-Mic mode, exercise caution to ensure the original dry signal is not mixed with Ocean Way Studio's processed output.

Reverb

In Reverb mode, the plug-in behaves like most reverb plug-ins; the modeled direct signal component is not included. Due to inherent nature of the Ocean Way Studios design, changes to the microphone Distance and Gain settings are less audible in Reverb mode than Re-Mic mode.

Studio Ocean Way Studios contains meticulous models of rooms A and B at Ocean Way Recording. Each room (Figure 101 below) has unique sonic characteristics.

Figure 107. Interior photos of Room A (left) and Room B (right) at Ocean Way Recording

OWR A

Ocean Way Recording A is Ocean Way's most spacious studio (45' x 52'), suitable for four-piece bands to full orchestras. With a rich sound, exceptionally clear low end, and super smooth decay, OWR A is a study in classic studio design. Associated artists include John Mayer and Whitney Houston, to classics like Frank Sinatra and Count Basie.

OWR B

Ocean Way Recording B is M.T. "Bill" Putnam's crowning achievement in studio design. This flawless miniature concert hall $(35' \times 45')$ makes recordings bigger than life. The separate isolation room $(18' \times 45')$ is a second studio ideal for guitars, providing an amazing response for distance micing. Radiohead and Green Day to Ray Charles and Duke Ellington have all made Room B their home.

Studio Menu

The Studio menu selects between the two recording rooms at Ocean Way Recording: OWR A and OWR B. To change the active studio, click the current studio name then select the desired room from the drop menu.

Tip: To change the studio room without altering the current microphone selections, press Shift on the computer keyboard while changing the studio selection.

Studio Defaults

When the studio is changed, the default settings for mic selections and distances are loaded for the near, mid, and far microphones. This menu does not change the mic filter, polarity, mute, balance, or level settings. A variety of audio sources (dispersion patterns) were modeled for Ocean Way Studios. The Source menu sets the optimum placement of the source within the room, as determined by the expertise of Allen Sides.

> Because an audio source's placement within a room determines the dispersion pattern of sound waves throughout the room, the active source can have a significant impact on the sound in the room.

> **Note:** Although the source placements are optimized for the source in the title (drums, strings, etc), any type of audio source can be used with any Source selection. Experimentation is encouraged.

Source Menu

Source

To change the active source, click the current source name then select the desired source from the drop menu. The current source is displayed in the menu and as an icon in the Position display panel.

The modeled sources (dispersion patterns) that are available in Ocean Way Studios are shown at right. "Cab" is short for electric guitar amplifier speaker cabinet. The letter is a brand name indicator.

Note: Cab O is available as a source only when Room B is active.

When the source is changed, the default source settings for mic selections and distances are loaded for the Near, Mid, and Far microphones. This menu does not change the microphone's Filter, Polarity, Mute, Balance, or Level settings.

Display Panels

The Display Panels show helpful information about the current state of the plug-in. The four available panels are shown in Figure 108. Click the buttons beneath the Display Panels to choose one. The button of the currently active panel is illuminated.

Note: The Display Panels are for informational purposes only. There are no parameter controls within any of the Display Panels, and the Panel selection controls cannot be automated.

Figure 108. The Display Panels

Position The Position panel shows an overhead representation of the current studio room. The relative positions of the source and active microphone(s) are displayed within the room.

The locations of the source and microphones within the room are determined by the Source and Distance parameters.

Note: Microphones that are muted are not shown in the Position Display Panel.

- Master EQThe Master EQ panel displays the state of the Master EQ settings. When the
Master EQ is disabled (or when both Master EQ Gain values are zero), the
frequency spectrum is flat.
- Interior The Interior panel displays a photograph of the currently selected studio. This panel is a helpful static background when visual feedback is undesirable.
- **Information** This panel displays information about the currently selected studio and microphone(s). General information is displayed initially; when the studio or microphones are changed, text in the panel is updated with information about the selection.
- Load Progress The Load Progress LED flashes when the plug-in is updating the impulse response, which is triggered whenever the Studio, Source, Mic Select, or

Mic Filter controls are modified. The new control settings are not heard until the LED stops flashing. Sonic artifacts and/or host CPU increases may occur during IR updating. See "Load Time" on page 346 for related information.

Note that studio and source changes take longer than microphone changes, because these changes update all three microphone pairs, while microphone changes update only one microphone pair.

Microphones

The Near, Mid, and Far microphone pairs each have their own set of controls. The control set for each mic is identical. See "Microphones Overview" on page 338 for related information.

Mic Selection	The microphones used in the room are selected with this menu. To change the active microphone, click the current microphone name then select the desired mic from the drop menu, or click the microphone image to cycle through the available microphones.
	Tip: To maintain the current Distance value for the selection when changing microphones, press Shift on the computer keyboard when making the mic selection.
	Not all microphones are available for all sources. For a list of available microphones and their descriptions, see Table 24 on page 338.
Distance	Distance varies the length between the microphone pair and the source. The available ranges and default values for Distance depend on the Studio and Source settings. Some microphones have fixed positions. See "Fixed Distance Microphones" on page 340 for details.
	Note: The colored rings around the encoders match the color of the micro- phone pair icons in the Position display panel for visual feedback.
	Tip: To return to the default value for the current microphone pair, click the DISTANCE text label.
	Note: Because these knobs are continuous "encoders" (they don't have end stops), mouse control is always linear even if controls mode is set to circular or relative circular.
Distance Delay	When a Distance encoder is clicked, the colored ring around the encoder changes to black and "aligned" is displayed as the value. When microphone pairs are aligned, the sonic character of their placement in the room is maintained, but the time delay between the source and the microphone that occurs in the physical realm is eliminated. Click the encoder a second time to return to normal Distance mode.
	For additional details about this feature, see "Distance Delay (Alianed) Over

For additional details about this feature, see "Distance Delay (Aligned) Overview" on page 340. For related information, see "Latency" on page 345. **Cut Filters** Independent High Cut and Low Cut filters can be enabled on each microphone. Click the switch to toggle the filter state. The filter is active when the switch is illuminated. The cutoff frequency and filter slope varies for each of the microphones, as shown in Table 27 below.

Table 27. Microphone Cut Filter values

High C (6 dB/0	ut Filter Octave)	Low Cut Filter (12 dB/Octave)	
Near	10 kHz	Near	50 Hz
Mid	8 kHz	Mid	75 Hz
Far	6 kHz	Far	150 Hz

Polarity Invert This switch inverts the polarity ("phase") of the microphone. The signal polarity is inverted when the switch is illuminated.

Polarity is especially useful when more than one microphone pair is enabled. See "Phase Considerations" on page 344 for related information.

Mute Mute turns off the microphone pair so it is no longer heard. Click the switch to toggle the mute state. When mute is active, the switch is illuminated, and the mic placement indicators are hidden from the Position Display.

Tip: To quickly solo any microphone pair, shift-click any Mute switch. When a Mute switch is shift-clicked, that mic is un-muted and the other mics are muted.

Balance Balance sets the position in the stereo panorama. When the plug-in is used in a mono-in/mono-out configuration, this control is locked in the center position.

Tip: To quickly return to the center position, click the BALANCE text label.

This fader controls the volume level of the microphone. Gain has a logarithmic taper for a more musical response. The gain range is off to +12 dB. Gain is at unity when set to the zero position.

Tip: To quickly return to the 0 dB (unity) position, click the associated NEAR/MID/FAR text label beneath the fader, or the associated "0" text label at the fader's unity gain position.

Master Controls

Predelay The amount of time between the dry signal and the onset of the reverb is controlled with this knob. The range is from 0 to 125 milliseconds.

Predelay is cumulative with the inherent microphone delays.

Note: Predelay is unavailable in Re-Mic mode.

Bypass disables the plug-in. The button glows red when Ocean Way Studios is disabled. Bypass can be used to compare the processed and original signals.

Note: The UAD DSP load is not reduced when bypassed with this switch. To reduce UAD DSP usage when bypassed, use the host's bypass switch instead.

L/R Swap This switch reverses the left and right channels at the output of the plug-in. L/R Swap is useful for changing the listener perspective from the audience position to the performer position. When the switch is not illuminated (the default), output is from the audience position.

Ocean Way Studios can be used in a mono-in/mono-out, mono-in/stereo out, or stereo-in/stereo-out configuration. The

left/right stereo outputs are summed to mono when the Mono switch is engaged. When the plug-in is used in a mono-in/mono-out configuration, this control is always engaged and the left/right output channels are summed.

PREDELAY

Gain

Mono

L/R

Mono Output

When the plug-in has monophonic output (when in a mono-out configuration or set to mono with the Mono switch), the microphone icon(s) in the Position panel shows a single icon for each active microphone, as shown at right. This is a convenient visual reminder that the plug-in output is monophonic.

Stereo Output

When the plug-in has stereo output, the microphone icon(s) in the Position panel shows dual icons representing the matched stereo set for each active microphone pair, as shown at right. Each microphone signal is routed to the left and right plug-in channel outputs respectively.

Tip: The color of the microphone

icons matches the color of the ring around each Distance knob for visual feedback.

Dry/Wet

When the plug-in is used in Reverb mode in a track insert (versus effect send/return) configuration, Dry/Wet determines the balance between the original dry signal and the processed signal. The range is from 0% (dry, unprocessed) to 100% (wet, processed signal only).

Dry/Wet is used to set the amount of ambience when the plug-in is used in a track insert (versus aux send/return) configuration.

Note: If Wet Solo is enabled, this control is unavailable.

Wet Solo Wet Solo puts Ocean Way Studios into 100% wet mode. When Wet Solo is on, it is the equivalent of setting the Dry/Wet knob value to 100%.

Wet Solo defaults to On, which is optimal when using Ocean Way Studios in Reverb mode in the "traditional" reverb configuration (placed on an effect group/bus that is configured for use with channel sends). When Ocean Way Studios is used on a channel insert in Reverb mode, this control should be deactivated so the Dry/Wet mix can be adjusted.

Wet Solo is fixed in the enabled position in Re-Mic mode so the original dry signal cannot be mixed with the modeled direct signal component within the plug-in.

This control uses a logarithmic taper to provide increased resolution when selecting lower values. When the knob is in the 12 o'clock position, the value is approximately 15%.

Note: Wet Solo is a global (per plug-in instance) control.

Master LevelThis fader controls the volume level at the output of the plug-in.
It has a logarithmic taper for a more musical response. The gain
range is from off to +12 dB. Gain is at unity when set to the zero
position.

Tip: To quickly return to the 0 dB (unity) position, click the MAS-TER text label beneath the fader, or the "0" text label at the fader's unity gain position.

Master EQ

This group of parameters contains the controls for Ocean Way Studio's master equalizer. It is a two band (low and high) shelving EQ that uses analog-sounding algorithms for great tonal shaping options. The slope of both filters is 12 dB per octave.

The Master EQ section is independent from the reverb algorithms. A graph of the current curve is displayed in the Master EQ display panel.

Tip: To quickly return to the 0 dB position for either of the Master EQ Gain controls, click the GAIN text label above the knob.

- Master EQThe Master EQ is enabled with this switch. The equalizer is active when the
button is illuminated.
- Low Shelf Frequency This parameter specifies the low shelving band transition frequency to be boosted or attenuated by the low shelf Gain setting. The range is from 20 Hz to 2 kHz.

Because this is a shelving EQ, all frequencies below this setting will be effected by the low shelf Gain value.

Low Shelf Gain This parameter determines the amount by which the transition frequency setting for the low band is boosted or attenuated. The available range is ± 12 dB.

High Shelf
FrequencyThis parameter determines the high shelving band transition frequency to be
boosted or attenuated by the high shelf Gain setting. The range is from 200
Hz to 20 kHz.

Because this is a shelving EQ, all frequencies above this setting will be affected by the high shelf Gain value.

High Shelf Gain This parameter determines the amount by which the frequency setting for the high band is boosted or attenuated. The available range is ± 12 dB.

The History of Ocean Way Recording

Ocean Way Recording in Hollywood California is the world's most awarded studio complex. Albums recorded at the studio have sold over 1 billion units. Generations of music icons, from Frank Sinatra, Nat King Cole, Ray Charles to The Rolling Stones, Eric Clapton, and Michael Jackson, all the way to contemporary artists like Green Day, Dr. Dre, Radiohead, Kanye West, and The Red Hot Chili Peppers, all choose Ocean Way for its phenomenal sounding rooms, customized equipment, impeccable electronic maintenance, and access to the music industry's most famous collection of vintage tube microphones.

In 1972, Allen Sides began building custom loudspeakers and leased a garage in Santa Monica, California as a hi-fi demo room. This garage was within steps of the Pacific Ocean and was situated on a street appropriately named - Ocean Way. Since he knew exactly what kinds of sounds were most impressive on his speakers, Sides did limited live to two-track recordings as demo material. During these demos, listeners became as interested in the recordings as the speakers and before long, they were asking Allen to make their recordings. In order to service those clients, Ocean Way Recording was born. Five Grammys and a thousand albums later Allen is still rolling.

Putnam moves to Los Angeles

In order to be a proper studio, Sides needed a recording console. This is where the story of Ocean Way truly begins; How Sides ended up purchasing Western Recorders' original tube console and came face to face with M.T. "Bill" Putnam. Putnam was a true renaissance man in the world of sound and music. His combined skills as a record producer, audio engineer, songwriter, singer, electrical engineer, inventor, studio owner and businessman are unparalleled to this day. Putnam owned and operated the largest independent recording facility in the country, Universal Recording in Chicago. But with a large chunk of his business moving west, clients like Frank Sinatra and Bing Crosby urged him to open a Los Angeles facility. Finally in 1957, Bill moved to 6050 Sunset Blvd. in Hollywood and started constructing brand new studios for his newly named studio enterprise, United Recording Corporation. The ultimate result was in 1961, when he purchased the neighboring Western Studio at 6000 Sunset, creating the United/Western Recorders studio complex.

A young Allen Sides in his natural element

Get This Stuff Out of Here So how was it that Allen Sides and Bill Putnam come together at this key moment? Sides explains, "I needed a console. I heard that Bill's factory manager Ray Combs needed to clear some space-much of it occupied by all the old tube equipment from United/Western Studios". Allen was a runner at United/Western in the late 60's and knew everyone, but had never met Bill. "I knew Bill was out of town, so I went to Ray and said, 'How about I give you \$6,000 for all this junk including the trailer in the back with the old Western console in it.' He said, 'I'll take it; get this stuff out of here.'"
"One man's junk is another man's treasure; and in this case, I was able to acquire some old Fairchild limiters, UA tube limiters, Macintosh tube amps, and enough equipment to completely fill my garage studio. It was the deal that really put me in business. However, there was a slight problem. I didn't actually have the 6 grand, so I wrote a check, picked up the stuff, and within six hours had sold enough gear to cover my check." When Putnam returned and found that his manager had been snookered into selling all this equipment for \$6,000, he wanted to meet him. As Sides explains, "There was no way to ever anticipate what would take place. When I walked into Bill's office, he gave me a long, stern look. That look eventually turned into a smile, and he proceeded to offer me a partnership which involved buying out studios all over the United States. Bill and I just clicked immediately and we became very good friends and business partners in the following years."

By 1976, things were going well at the Ocean Way garage, with sessions around the clock. Bill was a frequent guest and loved listening to the tri-amplified front loaded theater horns in Allen's control room. Unfortunately, trying to keep a low profile while running a commercial studio in a quiet residential neighborhood proved to be much more tricky.

The Opportunity of a Lifetime

As fate would have it, a lease was about to expire for Studio B in the United building. When Sides approached his friend about leasing the studio, Bill offered him a "sweetheart deal" on the space. Sides quickly redesigned and rebuilt the Studio B control room, and moved all his equipment in. Studio B was an

astounding acoustic space and Sides was thrilled. Bill felt that of all the rooms he had designed and built, this was his favorite and he was very pleased that his protégé would carry on the tradition.

Early sessions ranged from Neil Diamond, Chick Corea, Bette Midler, and all the way to Frank Zappa. In 1982 towards the end of his career, Bill also leased Studio A to Allen. Sides made a few control room changes, and Studio A immediately became one of the most popular rooms in town again. One of the first projects was Lionel Ritchie's "Can't Slow Down," which sold 25 million records and Michael Jackson's Thriller. Lionel and Michael became two of Allen's best long term clients. A couple years later, Bill sold United/Western to Allen, at which time United Recorders then became Ocean Way Recording. It was also during this time Sides began buying close to a thousand tube microphones from overseas: The European studios and broadcasters were dumping loads of "antiquated" tube mics for brand new phantom-powered transistor mics. He carefully went through every mic, picking the absolutely best of the best and selling off the rest. This is how, along with mics from previous studio buyouts with Putnam, Ocean Way amassed one of the largest collection of tube mics in the world.

A New Era Now the Hollywood Studio has changed hands again after nearly 30 years. Neighboring Sunset/Gower Soundstage now has purchased the studios and equipment from Allen and entered into a licensing agreement to keep Ocean Way and its staff in place, acquiring the studios to form a "strategic alliance" between their 100-year-old film and TV studios and soundstages and the neighboring music recording studios, creating one unified production complex. Allen Sides continues to consult

cording projects.

The original control rooms and recording spaces have always stayed true to Putnam's designs, and those

and work at the studios on all his re-

rooms will remain untouched under the new ownership - with top staff and equipment in place. According to Ocean Way's new day-to-day manager Robin Godchild, the studios are still very much available for commercial bookings, and clients can expect to see some improvements and additions in the coming months.

Ocean Way Recording is now captured as a tool developed by Universal Audio and Allen Sides. The Ocean Way Studios plug-in rewrites the book on what's possible with acoustic space emulation.

CHAPTER 33

Precision Buss Compressor

Overview

The Precision Buss Compressor is a dual-VCA-type dynamic processor that yields modern, transparent gain reduction characteristics. It is specifically designed to "glue" mix elements together for that cohesive and polished sound typical of master section console compressors. A flexible and intuitive tool, the Precision Buss Compressor is intended primarily for controlling the final output of your mix, but can be usefully applied to a variety of sources from drum busses or overheads to vocal groups, or even as a channel compressor on individual track inserts.

The Precision Buss Compressor's control set features Threshold, Ratio, Attack and Release, with all parameters specifically tailored to buss compressor usage. The Release control includes a multi-stage Auto Release also designed for a wide variety of program material. Input and Output Gain control is offered with metering for input, output and gain reduction. A high pass Filter is offered for the internal control signal sidechain to reduce the sensitivity of the compression to lower frequencies while retaining them in the output signal. An automatic Fade feature is included, which allows the user to set a custom fade-out or fade-in of the mix between 1 and 60 seconds long. Rounding out the feature set is a Mix control that allows the user to achieve "parallel" style dynamics control, without the need for a second buss or channel.

Precision Buss Compressor Screenshot

Figure 109. The Precision Buss Compressor plug-in window

Precision Buss Compressor Controls

Control knobs for the Precision Buss Compressor behave the same way as with all UAD plug-ins. Parameters with text values can be modified with text entry.

Filter

Filter regulates the cutoff frequency of the filter on the compressor's control signal sidechain. Removing low-frequency content from the sidechain can reduce excessive gain reduction and/or "pumping" on bass-heavy audio signals without reducing bass content of the audio signal itself.

The filter is an 18 dB per octave, coincident-pole high-pass filter. The available range is 20 Hz–500 Hz and Off.

Note: The Filter parameter affects the control signal (sidechain) of the compressor only. It does not filter the audio signal.

Threshold

This parameter determines the threshold level for the onset of compression. Incoming signals that exceed this level are compressed. Signals below the level are unaffected.

The available threshold range depends on ratio setting. At higher Ratio values, more headroom is available. Since the

plug-in is designed primarily as a buss compressor, where signal levels typically run hotter than individual tracks, this feature increases the control resolution for fine-tuning these higher levels. When Ratio is changed, the Threshold value is updated accordingly:

When Ratio is set to 2:1, the Threshold range is -55 dB to 0 dB.

When Ratio is set to 4:1, the Threshold range is -45 dB to +10 dB.

When Ratio is set to 10:1, the Threshold range is -40 dB to +15 dB.

Note: When Ratio is changed, Threshold numerical values are updated but the Threshold knob position does not move.

As the Threshold control is decreased and more compression occurs, output level is typically reduced. Adjust the Gain control to modify the output to compensate if desired.

Ratio

Ratio determines the amount of gain reduction for the compressor. For example, a 2:1 ratio reduces the signal above the threshold by half, with an input signal of 20 dB being reduced to 10 dB.

The available Ratio values are 2:1 (default), 4:1, and 10:1.

Attack

Attack sets the amount of time that must elapse once the input signal reaches the Threshold level before compression is applied. The faster the Attack, the more rapidly compression is applied to signals above the threshold.

The Attack range is from 0.10 milliseconds to 32 milliseconds. The availability of relatively slow attack times (as compared to other compressors) is one factor that can provide the in-your-face-pumping quality that is so popular with large console VCA-style compressors.

Release

Release sets the amount of time it takes for compression to cease once the input signal drops below the threshold level.

The available range is from 0.10 seconds to 1.20 seconds, with Automatic release available at the full-clockwise position.

The Auto release characteristic for Precision Buss Compressor has a unique quality that is optimized for program material.

Slower release times can smooth the transition that occurs when the signal dips below the threshold, especially useful for material with frequent peaks. However, if you set too large of a Release time, compression for sections of audio with loud signals may extend to lengthy sections of audio with lower signals.

The Precision Buss Compressor provides a Fade function that, upon activation, automatically reduces the plug-in output to minimum within a specified time period. This function enables extremely smooth-sounding fade outs (and fade ins), plus it can be automated as well. The Fade function processes the signal at the output of the compressor.

Fade

Fade Set

Fade Set determines the amount of time that will pass between the Fade button being activated and the plug-in output level being reduced to minimum (or being raised to 0 dB in the case of a fade in). The available range is from 1.0 second to 60 seconds.

Fade times immediately reflect the current Fade Set value. Therefore a fade out that has already been initiated can be accelerated by changing Fade Set during the fade out. Conversely, a fade in can be accelerated by changing Fade Set during the fade in.

Note that although the Fade Set control itself has linear taper, the fade signal level that is output has an exponential curve.

FADE Fade Switch

Activating the Fade switch initiates a fade out. The fade out time is determined by the Fade Set parameter.

The Fade switch flashes red when a fade out is in progress, and glows solid red when the fade out is complete (when the Fade Set time has elapsed).

Deactivating Fade initiates a fade in. During a fade in, the signal level is increased from the current level of attenuation to 0 dB of attenuation. The Fade switch flashes blue when a fade in is in

progress, and is no longer illuminated when the fade in is complete (when the Fade Set time has elapsed).

Toggling the Fade switch causes an already active fade to reverse direction, without a jump in output level. The Fade Set rate is constant even if an active fade is interrupted. For example: If the Fade Set value is 30 seconds and a fade out is initiated, then Fade is clicked again after 20 seconds, it will take 20 seconds to fade back in.

Note: Shift+click the Fade button to instantly return the level back to 0 dB (this feature cannot be automated).

Input Level

Input controls the signal level that is input to the plug-in. Increasing the input may result in more compression, depending on the values of the Threshold and Ratio parameters.

The default value is 0 dB. The available range is ±20 dB.

Mix

The Mix control determines the balance between the original and the processed signal. The range is from 0% (dry unprocessed signal only) to 100% (wet processed signal only). The default value is 100%.

Output Level

Output controls the signal level that is output from the plug-in. The default value is 0 dB. The available range is ±20 dB.

Output controls both the dry unprocessed and wet processed signals (as determined by the Mix control).

Generally speaking, adjust the Output control after the desired amount of compression is achieved with the Threshold and Ratio controls. Output does not affect the amount of compression.

Level Meters

The stereo peak/hold Input and Output Meters display the signal level at the input and output of the plug-in.

The range is from –30 dB to 0 dB. Signal peaks are held for 3 seconds before resetting.

Gain Reduction Meter

The Gain Reduction meter displays the amount of gain reduction occurring within the compressor.

More blue bars moving to the left indicate more gain reduction is occurring.

The meter range is from –16 dB to 0 dB. Signal peaks are held for 3 seconds before resetting.

Power

The Power switch determines whether the plug-in is active. Click the toggle button or the UA logo to change the state.

When the Power switch is in the Off position, plug-in processing is disabled and UAD DSP usage is reduced (unless UAD-

2 DSP LoadLock is enabled). When the plug-in is bypassed with this switch (but not by the host bypass), the I/O meters and the Input Level knob remain active.

CHAPTER 34

Precision De-Esser

Overview

The Precision De-Esser seamlessly and accurately removes sibilance from individual audio tracks or even composite mixes via its intuitive interface and sophisticated yet transparent filter processing.

The Threshold knob dials in the amount of sibilance reduction, while the twoposition "Speed" button gives control over the envelope (attack and release) of the detector. The Frequency knob sweeps a continuous target frequency range from 2-16 kHz, allowing repairs on a large range of voices (or even overheads and hi-hats), while the Solo button allows the user to isolate and monitor the target sibilant frequencies. The Width control offers a variable 1/6 to 1 2/3 octave bandpass filter that is perfect for complex program material, adapting technology from the TEC-nominated Precision Multiband. The Width control also switches into a more traditional highpass filter more commonly employed when tailoring individual voices. For even greater transparency, the Split feature gives the user the option to compress only the sibilant range, or may be turned off to compress the entire spectrum for more traditional de-essing.

Precision De-Esser Screenshot

Figure 110. The Precision De-Esser plug-in window

Precision De-Esser Controls

Control knobs for the Precision De-Esser behave the same way as all UAD plug-ins. Threshold, Frequency, and Width values can be modified with text entry.

Threshold

Threshold controls the amount of de-essing by defining the signal level at which the processor is activated. Rotate Threshold counter-clockwise for more de-essing.

Signals peaks as determined by Frequency ("Fre-

quency" on page 371) and Width ("Width" on page 372) that exceed the Threshold level are compressed by a ratio of 7:1.

The available range is -40 dB to 0 dB.

Speed

Speed determines the response of the sibilance detector. Fast mode will usually make sibilance reduction more obvious. In Slow mode the effect is usually more subtle but can produce a more naturalsounding result. The actual times of the two modes are as follows:

- Fast: Attack = 0.5ms, Release = 30ms.
- Slow: Attack = 2.0ms, Release = 120ms.

Click the Speed button to change the mode. Alternately, you can click+hold the LED area and drag like a slider to change the value.

Frequency

Solo

This control defines the center frequency of the de-esser when in bandpass mode, or the cutoff frequency of the de-esser when in highpass mode. For bandpass use, the value is set to the center of the undesirable fre-

quency range that is to be reduced. For highpass use, the value is set below the frequency range that is to be reduced. Used in conjunction with the Width control ("Width" on page 372), a broad range of de-essing is possible.

The available range is 2 kHz – 16 kHz.

The Solo button isolates the de-essing sidechain (the signal defined by Frequency and Width). Solo makes it easier to hear the problem frequencies to be attenuated.

Click the button to active Solo mode. The button is red when Solo is active.

Note: When Solo is active, changes to the Threshold and Split controls cannot be heard.

Width

SPLIT

Width controls the bandwidth of the de-essing sidechain when in bandpass mode. Bandpass mode is active when the control is in any position except fully clockwise.

Smaller values have a narrower bandwidth, causing a tighter, more focused de-essing effect. Higher values have wider bandwidth, for de-essing when undesirable frequency ranges are broader.

When Width is rotated fully clockwise, High Pass mode is activated. In High Pass mode, Frequency ("Frequency" on page 371) defines the cutoff frequency of the high pass filter (instead of the center frequency of the bandpass filter). High Pass mode is useful when you want to attenuate all frequencies above the cutoff frequency.

The available range is 0.15 (about 1/6 octave) to 1.61 (about 1 2/3 octaves), plus High Pass mode.

Note: UAD DSP usage is slightly decreased when Precision De-Esser is in High Pass mode versus bandpass mode (unless UAD-2 DSP LoadLock is enabled).

Split

Split determines if attenuation (compression) is applied to the sidechain signal only, or to the entire audio signal.

In normal use Split should be enabled, causing only the "ess" spectrum as defined by Frequency and Width (i.e., the sidechain), to be attenuated. This provides the most precise de-essing control.

Split can be disabled, which causes the entire input signal to be attenuated (instead of just the "ess" sidechain) which results in more traditional compression. However, the sidechain still controls attenuation when Split is off.

Click the Split button to change the mode. Alternately, you can click+hold the LED area and drag like a slider to change the value.

Note: UAD DSP usage is slightly decreased when Split is disabled (unless UAD-2 DSP LoadLock is enabled).

Gain Reduction

The Gain Reduction meter provides a visual indication of how much attenuation (compression) is occuring. Signal peaks are held for 3 seconds before resetting.

When Split is on, the amount of sidechain attenuation is displayed. When Split is off, it displays the attenuation of the entire signal.

Power

The Power switch determines whether the plug-in is active. This is useful for comparing the processed settings to the original signal or bypassing the plug-in to reduce the UAD DSP load (load is not reduced if UAD-2 DSP LoadLock is enabled).

Toggle the switch to change the Power state; the UA logo is illuminated in blue when the plug-in is active.

Note: You can click-hold the power switch then drag it like a slider to quickly compare the enabled/disabled state.

Operating Tips

- For taming sibilance for a full mix/mastering, best results will usually be obtained by enabling Highpass and Split modes.
- Generally, female "ess" and "shh" sounds vary more in frequency than those of males. Due to this situation, you may find that using the sidechain filter in Highpass mode (or Bandpass mode with a large width) may be more responsive.
- Over de-essing can degrade the natural sound of a vocal.

CHAPTER 35

Precision Enhancer Hz

Overview

The Precision Enhancer Hz allows the user to selectively add upper harmonics to bass fundamentals, sometimes referred to as "phantom bass." This significantly enhances the perception of low-end energy beyond the conventional frequency response of small speakers. These harmonics stimulate a psychoacoustic bass-enhancing effect in the listener, giving even the smallest speakers greater translation of low frequency sources. Universal Audio's unique approach to this common problem combines a simple control set that yields exacting results with minimal adjustment and allows the widest range of tonality available in its class, from subtle to decidedly audible.

The Hz Frequency control sets the corner frequency of the bass-isolation low pass filter, while Effect blends the generated signal into the original signal. Four effect slopes are available for variations in harmonic density, while five modes present various internal control configurations to support the widest array of source material. Finally, the Precision Enhancer Hz includes control over the final output with metering to compensate for gain changes created by the effect.

Precision Enhancer Hz does for low frequencies what Precision Enhancer kHz does for the highs. Together, they are a great complementary pair.

Precision Enhancer Hz Screenshot

Figure 111. The Precision Enhancer Hz plug-in window

Precision Enhancer Hz Controls

Control knobs for the Precision Enhancer Hz behave the same way as with all UAD plug-ins. Effect, Hz Frequency, and Output values can be modified with text entry.

Effect Knob	The Effect Knob controls the amount of pro- cessing that occurs in the plug-in. The avail- able range is from 0.00 to 100.0%.	
	Technically speaking, Effect scales the input to the enhancer. Increasing this parameter makes the enhancer have a higher amplitude output for a given input level. Increasing Effect increases the overall enhancement effect.	
	Note: The signal level at the plug-in input will interact with the Effect control.	
Effect Meter	The Effect Meter indicates the amount of signal processing that is occurring. More illuminated blue segments indicate more signal enhancement.	
Effect Solo	Effect Solo isolates the generated signal and is affected by Effect level.	
	The Effect Solo signal is "pure" and contains no added original or fil- tered bass signal. Therefore the soloed signal may not sound "pleasant" when heard by itself. When Effect Solo is used in conjunction with "Hz Solo" on page 377, the complete "mixed" effect is heard.	
Mode	The five Modes (A, B, C, D, and "All") optimize the plug-in internally to support the widest array of source material. The Mode control determines the type of enhancement that will be applied to the signal.	
	Tip: The active Mode can be selected by clicking the Mode button repeatedly to rotate through the Modes, or by clicking each Mode letter or LED.	

Mode A (Bass 1)

Mode A is tuned for both acoustic and electric bass instruments. Adds low frequency emphasis when set to low frequency value, mid to high frequencies aid in phantom bass generation for smaller sound systems.

Mode B (Bass 2)

Mode B is primarily for electric and DI bass with balanced mid range harmonics to help the bass stick out of the mix.

Mode C (Synth)

Mode C is tuned specifically for synth bass and other full-range material. It produces a wider range of harmonics than the Bass modes A and B. Mode C also works well on sub-mixes and program material. Moderate compression is applied to the harmonics signal, increasing the amplitude of the harmonics and altering their timbre.

Mode D (Kick)

Mode D has a short decay, which makes this setting ideal for kick drum sounds and other percussive instruments. Moderate compression is applied to the harmonics signal, increasing the amplitude of the harmonics and altering their timbre.

All Mode

All mode offers a more exaggerated and audible effect for creative purposes or when less subtle results are desired. Compression is applied to the harmonics signal, increasing

the amplitude of the harmonics and altering their timbre. The frequency range is similar to Mode A.

Tip: "All" mode can be selected by shift+clicking Mode letters or LEDs.

Slope

Slope changes the shape of the high pass filter that is applied to the effect signal. The high pass filter helps eliminate rumble/muddiness in the signal.

Slope can be set to 6, 12, 24, or 36 dB per octave. The active Slope can be selected by clicking the Slope button repeatedly to rotate through the values, or by clicking each Slope value or LED.

Note: When the Hz Frequency is set to a low value, Slope may have little or no audible effect.

Hz Frequency

Through filter isolation of the original bass content, the Hz Frequency parameter defines the cutoff frequency for the enhancement process. Frequencies below this value are enhanced by the processor. The available range is 16 Hz to 320 Hz.

Hz Solo Hz Solo isolates the original bass signal and can be combined with Effect Solo. Hz Solo is active when the button is red.

Output

Output controls the signal level that is output from the plug-in. The available range is -20 dB to 0 dB.

Generally speaking, adjust the Output control

after the desired amount of processing is achieved with the Effect and Hz Frequency controls. Output does not affect the amount of enhancement processing, nor does it have any effect when the plug-in is disabled.

Output Meter

The stereo Output Meter displays the signal level at the output of the plug-in.

When the plug-in is disabled with the plug-in Power switch (but not the host plug-in enable switch), the output meters still function.

Power

The Power switch determines whether the plug-in is active. This is useful for comparing the processed settings to the original signal or bypassing the plug-in to reduce the UAD DSP load (load is not reduced if UAD-2 DSP LoadLock is enabled).

Toggle the switch or click the UA logo to change the Power state. The UA logo is illuminated in blue when the plug-in is active.

Note: You can click-hold the power switch then drag it like a slider to quickly compare the enabled/disabled state.

Precision Enhancer Hz Usage Notes

- The Precision Enhancer Hz effect can serve multiple purposes. When the frequency control is set low, the effect extends into the audible low end. Lower frequencies work well for adding a low end thump or beefing up percussive bass/kicks, but be careful not to overdo it. With the frequency control set to mid to higher frequencies, the effect is designed to add bass tone that would ordinarily disappear on smaller speakers.
- For the most predictable results, it is recommended to audition your mix on both full range systems with a subwoofer, as well as small consumer systems such as a boombox or computer speakers.
- A different effect response will be achieved when the plug-in is used precompression. It is recommended to experiment with processing order as results can vary substantially.

CHAPTER 36

Precision Enhancer kHz

Overview

The Precision Enhancer kHz is a sophisticated tool with a simple control set, primarily designed to bring dull or poorly recorded tracks to life. However, with five distinct Enhancement "Modes", the Precision Enhancer kHz will find uses on virtually any source. It can be used to minimally massage the middle and upper frequencies of a mix, or drastically alter the presence or dynamics of individual tracks or groups; Unlike other enhancers that function by frequency delay or filtered clipping, the Precision Enhancer kHz works on specialized techniques of equalization and dynamic expansion that can be used as a highly versatile effect.

The five Modes (A, B, C, D and the shift-clickable "All") present various control configurations to support the widest array of source material. With Modes A and B, the filtered audio is mixed in with the dry signal according to the Effect control. For Modes C, D and All, audio is passed through a unique upwards expander where the expanded audio is then filtered before being mixed with the dry signal. For these modes, Effect is used as a fader on the way into the expander. The release can be adjusted to either Fast or Slow via the Speed button, giving a greater range of dynamic/frequency enhancement. For Mode C, the sweepable filter applied to the expander's output is identical to the filter used with Mode A. For Mode D and All, the expander's output is passed to a set of filters in parallel. Finally, the Precision Enhancer kHz includes control over the final Output level metering to compensate for gain changes created by the effect.

Precision Enhancer kHz Screenshot

Figure 112. The Precision Enhancer kHz plug-in window

Precision Enhancer kHz Controls

Control knobs for the Precision Enhancer kHz behave the same way as with all UAD plug-ins. Effect, kHz Frequency, and Output values can be modified with text entry.

Effect Knob

The Effect Knob controls the amount of processing that occurs in the plug-in. The available range is from 0.00 to 100.0%.

Technically speaking, Effect scales the input

to the enhancer. Increasing this parameter makes the enhancer have a higher amplitude output for a given input level. Increasing Effect increases the overall enhancement effect.

Note: The signal level at the plug-in input will interact with the Effect control.

Effect Meter The Effect Meter indicates the amount of signal processing that is occurring. More illuminated blue segments indicate more signal enhancement.

Mode

MODE B C

The Mode control determines the type of enhancement that will be applied to the signal. The active Mode can be selected by clicking the Mode button repeatedly to rotate

through the Modes, or by clicking each Mode letter or LED. "All" mode is selected by shift+clicking Mode letters or LEDs.

Mode A

Mode A enhances the high frequency content statically. Input dynamics do not affect on the enhancement process.

Mode B

Mode B is optimized for vocal range content. The kHz Frequency parameter is disabled in this mode.

Mode C

Mode C dynamically enhances the high frequency content. The enhancement amount is increased as the input signal level increases.

Mode D

Mode D dynamically enhances both high and low frequency content. The enhancement amount is increased as the input signal level increases. The kHz Frequency parameter is disabled in this mode.

All Mode

"All" mode is selected by shift+clicking Mode letters or LEDs. All Mode expands all frequencies of the input signal. The enhancement amount is increased as the input signal level increases. The kHz Frequency parameter is disabled in this mode.

SPEED

The Speed parameter defines the attack and release characteristic of the enhancement process.

Fast

In Fast mode, the enhancement processor has a quick response time of 30ms, which yields a more percussive "bite" and/or a more aggressive sound.

Slow

Slow mode has a slower response time of 180ms which can deliver a smoother sound overall.

kHz Frequency

FAST

SLOW

The kHz Frequency parameter defines the cutoff frequency for the enhancement process in Mode A and Mode C. Frequencies above this value are enhanced by the processor. The available range is 1.00 kHz to 10.0 kHz.

Note: kHz Frequency is disabled in Modes B/D/All.

Output

Output controls the signal level that is output from the plug-in. The available range is -20 dB to 0 dB.

Generally speaking, adjust the Output control after the desired amount of processing is achieved with the Effect and kHz Frequency controls. Output does not affect the amount of enhancement processing, nor does it have any effect when the plug-in is disabled.

Output Meter

The Output Meter displays the signal level at the output of the plug-in.

When the plug-in is disabled with the plug-in Power switch (but not the host plug-in enable switch), the output meters still function.

Power

The Power switch determines whether the plug-in is active. This is useful for comparing the processed settings to the original signal or bypassing the plug-in to reduce the UAD DSP load (load is not reduced if UAD-2 DSP LoadLock is enabled).

Toggle the switch or click the UA logo to change the Power state; the UA logo is illuminated in blue when the plug-in is active.

Note: You can click-hold the power switch then drag it like a slider to quickly compare the enabled/disabled state.

CHAPTER 37

Precision Equalizer

Overview

The Universal Audio Precision Equalizer[™] is a stereo or dual-mono four band EQ and high-pass filter designed primarily for mastering program material. The Precision Equalizer may also be used in recording and mixing where the utmost in EQ quality is required. The Precision Equalizer is based on industry standard analog mastering filters, and uses the classic parametric controls arrangement. The Precision Equalizer utilizes the best from those designs while incorporating features convenient to digital mastering. To preserve the greatest sonic detail and ensure a minimum of artifacts in the upper frequency range, the Precision Equalizer is upsampled to 192 kHz.

Precision Equalizer Screenshot

Figure 113. The UAD Precision Equalizer plug-in window

Precision Equalizer Controls

The easy to use Precision Equalizer features stepped controls throughout for easy recall. Both the left and right channels feature four bands of EQ, grouped in two overlapping pairs. There are two bands for low frequencies (L1 and L2), and two for highs (H1 and H2). There is also a shelving or peak/notch filter available for each band, along with five peak/notch (Q) responses per band. The high-pass filter is a far-reaching 18 dB per octave, which enables precise filtering of power-robbing sub-harmonic content, or other creative uses.

The Precision Equalizer also features flexibility in auditioning. There are three separate EQ configurations, allowing selection of two complete sets of stereo parameters or the Dual mode when disparate channel adjustments are necessary. In addition, parameter values can be easily transferred between parameter groups using the Copy buttons.

Control Grouping

The L and R equalizer sections are independent groups of parameters, each controlling one side (left or right) of the stereo source signal.

The L and R controls are linked except when in Dual mode. In Dual mode, control groups L and R can be independently adjusted.

Modes

The Mode switches define the operating mode of Precision Equalizer. The currently active mode is indicated by a blue light. Each mode is detailed below.

Stereo Mode In Stereo mode, the L and R equalizer sections both control one side of the stereo source signal. The L and R controls are linked in stereo mode.

In stereo mode there are two sets of EQ settings (referred to as A and B), with each set containing the full set of L and R parameter values (the high-pass filter value is global per preset). This feature enables easy switching between two EQ settings for comparison purposes. Both the A and B parameter sets are contained within a single Precision Equalizer preset. **Dual Mode** In Dual mode (dual-mono mode), the left and right parameters can be independently adjusted so that each side of the stereo signal can have different EQ settings. Note that this mode is infrequently used during mastering because phase, imaging, and level inconsistencies may be induced in the resulting stereo signal.

Mode Selection

Any of the below methods may be used to modify the Mode value:

- Click the Stereo button to cycle through modes A and B
- Click the Dual button to activate dual-mono mode
- Click the indicator light above each mode
- Click+hold+drag the indicator light above each mode.

Parameter Copy Buttons The Parameter Copy buttons provide an easy method for copying parameter values. The behavior of the buttons is determined by the current operating mode of Precision Equalizer.

Note: The values that existed at the destination before copying are lost.

Stereo Mode

When in Stereo mode (see "Stereo Mode" on page 384), clicking A > B copies the left AND right parameter values from parameter set A to parameter set B, and clicking the A < B button copies all the values from parameter set B to parameter set A.

This feature is useful when you want to make an EQ change to a stereo signal while maintaining the original values so the two settings can be easily compared.

Note: The high-pass filter parameter is global per preset and is not affected by this control.

Parameter Copy in Dual Mode

When in Dual mode, the A and B buttons behave as left and right channel copy buttons. Clicking A > B copies all the values from the left channel parameters to the right channel parameters, and clicking A < B copies all the values from the right channel parameters to the left channel parameters.

Power Switch

The Power Switch determines whether the plug-in is active. This is useful for comparing the processed settings to the original signal, or to bypass the plug-in to reduce the UAD DSP load (load is not reduced if UAD-2 DSP LoadLock is enabled).

Click the rocker switch to change the Power state. Alternately, you can click the blue UA logo to toggle the Power

state.

Band Controls

Each control set (L and R) has four EQ bands. Two bands are overlapping low frequency bands labeled L1 and L2, and two bands are overlapping high frequency bands labeled H1 and H2.

Each of the four bands has a control for bandwidth, enable, frequency, and gain. All four of the EQ bands can be used in parametric or shelf mode. The controls are exactly the same for each band; only the available frequency values differ.

Bandwidth Knob The Bandwidth (Q) knob defines the proportion of frequencies surrounding the band center frequency to be affected by the band gain control.

The numbers represent the filter slope in dB per octave. The available selections are 4, 6, 9, 14, 20, and Shelf.

When set to Shelf on the L1 and L2 bands, the band becomes a low shelving filter. When set to Shelf on the H1 and H2 bands, the band becomes a high shelving filter.

Band Enable Button

Each band can be individually engaged with the Enable button. All bands default to disabled. When a band is enabled, the button glows blue. To enable a band, click the Enable button or move the band Gain knob.

You can use these buttons to compare the band settings to that of the original signal, or to bypass the individual band. UAD DSP usage is slightly decreased when a band is disabled (unless

UAD-2 DSP LoadLock is enabled).

Frequency Knob The Frequency knob determines the center frequency of the filter band to be boosted or attenuated by the band Gain setting.

This knob is stepped with 41 values for easy reproducibility during mastering. To double the resolution of the available knob values (for fine control), press the shift key on the computer keyboard while adjusting the knob. This increased 2x frequency resolution (within the available range) can also be specified using text entry, parameter automation, or 'controls' mode. The available values for each of the four bands is the same in both parametric and shelf modes, and are listed in Table 28 below.

Note: Not all host applications support automation and/or controls mode.

Table 28. Precision Equalizer Band Frequency Ranges

Low Frequencies (L1 and L2)	19 – 572 Hertz
High Frequencies (H1 and H2)	617 – 27k Hertz

Gain Knob The Gain knob determines the amount by which the frequency setting for the band is boosted or attenuated. The available Gain values are listed in Table 29 below.

Table 29. Precision Equalizer band gain values

0.0 dB	±2.0 dB	±5.0 dB
±0.5 dB	±2.5 dB	±6.0 dB
±1.0 dB	±3.0 dB	±8.0 dB
±1.5 dB	±4.0 dB	

High-Pass Filter

The high-pass filter is useful for reducing low frequency content. It is a global filter; it always affects both left and right channels, regardless of the active mode. See Table 30 below for available settings.

Table 30. Precision Equalizer high-pass filter frequencies

-	
Off (disabled)	40 Hz
10 Hz	60 Hz
20 Hz	80 Hz
30 Hz	100 Hz

Precision Equalizer Latency

The Precision Equalizer uses an internal sample rate of 192 kHz to facilitate its amazing sonic quality. This upsampling results in a slightly larger latency than other UAD plug-ins. See See "Upsampled Plug-Ins" on page 563. for more information.

Note: Compensating for Precision Equalizer is not required if the host application supports full plug-in delay compensation throughout the signal path, or when it is used only on the outputs.UAD-2 DSP LoadLock

Precision K-Stereo Ambience Recovery

Psychoacoustic Ambience Recovery and Stereo Processor Created by Mastering Engineer Bob Katz

Universal Audio's Precision K-Stereo[™] Ambience Recovery plug-in is a psychoacoustic processor conceived and created by famed mastering engineer Bob Katz. Collaborating with Universal Audio to bring this unique, patented process to the UAD platform, Bob Katz's K-Stereo process uses elements of the Haas effect and other psychoacoustic principles to create a transparent, phase-accurate "ambience recovery" and stereo enhancement tool. Primarily designed for critical 2-track mastering applications, Precision K-Stereo extracts the ambient cues inherent in the source recording and provides features capable of spreading the uncorrelated ambience around the soundstage, enlarging the size of the soundstage both deeper and wider. It also increases the clarity and localization of the source material within its algorithm while increasing the third dimension of the sound. Precision K-Stereo does not have a sound of its own—it transparently enhances the existing ambience and early reflections of your sources to breathe new life into busy or narrow-sounding mixes. Precision K-Stereo enhances the depth and imaging of the instruments and vocals on your stereo master without adding artificial reverberation, or changing the ratio of center elements to side elements, thus providing a do-noharm approach to finalizing the stereo image of your critical mix source material.

Precision K-Stereo Screenshot

Figure 114. The Precision K-Stereo plug-in window

Operational Overview

Ambience Recovery	The primary function of Precision K-Stereo is for ambience recovery and en- hancement. The plug-in doesn't add new ambience or change the balance of the mix. Instead, it extracts, recovers, polishes, and embellishes the ambience that already exists in a source recording.
	Precision K-Stereo does not use any comb filters, matrixing, phase processing, or related techniques which are used in typical image processors. Instead, the ambience recovery process is accomplished using established psychoacous- tic principles. The result is a smooth, natural, phase-coherent, and mono-com- patible sound that meets professional mastering standards.
	In addition to ambience level and enhancement adjustments, the ambient por- tion of the source material can be further equalized using low/high cut filters and a fully parametric bell filter. These ambience filters affect the "wet" signal only and are completely independent from the "dry" portion of the recording.
Primary Application	Precision K-Stereo is designed for use during the mastering process to fine- tune the ambience that exists in previously-mixed stereo program material. Generally speaking, adjusting ambience during multitrack mixdown is best managed within the mix itself because of the higher level of control and detail available at that stage.
	Of course, Precision K-Stereo can be used across the stereo bus during mixing and/or in other creative applications as well. However, since the process is optimized for broad spectrum mixes with at least some ambient content, the effect may be extremely subtle on individual tracks, depending on the ambi- ent content in the recording.
Mid/Side Leveling	The Precision K-Stereo processor does not use or require mid/side encoding or decoding techniques to achieve ambience recovery nor enhancement. However, the plug-in has an independent mid/side ratio leveling feature that can be useful during mastering to compensate for overall center-to-side level imbalances within the stereo field.
	The ambience recovery feature can then be used to recover ambience and space that is lost when the mid-channel level is increased (such as when rais- ing a center-located vocal or instrument).

Configurations	Precision K-Stereo is optimized for use in stereo-in/stereo-out configurations. However, ambience recovery is possible on monophonic source recordings when the plug-in is used in a mono-in/stereo-out configuration. Mono signals are "stereo-ized" in the MISO context.		
	Note: Due to the inherent stereo nature of the ambience recovery process, Precision K-Stereo is not intended for use in mono-in/mono-out configurations.		
Presets	Precision K-Stereo includes factory presets designed by Bob Katz. A list of these presets and their application notes are at the end of this chapter.		

Blog Article by Bob Katz

Bob Katz has contributed a blog article that contains lots of interesting details and application tips for Precision K-Stereo. The article is published on our website:

• www.uaudio.com/blog/k-stereo-tips-and-tricks.html

Precision K-Stereo Controls

Control Arrangements Precision K-Stereo controls are grouped into four sections: Ambience Recovery, Ambience Filters (EQ), Mid/Side, and L/R Gain. The detailed control descriptions are similarly grouped.

Control Adjustments Switches For the main switches (Recover, EQ, etc.), click the switch to toggle the setting. The switch is engaged when it is illuminated.

Precision K-Stereo switch engaged (left) and disabled (right).

Knobs

For the knob controls, values can be adjusted with the mouse or values can be entered directly via text entry. Additionally, when the tickmarks and/or values around the knob are clicked, the knob will jump to that setting. The "big knobs" (Ambience Gain, Mid/Side Gain, and L/R Gain) can be returned to the zero value by clicking the control label above the knobs.

Ambience Recovery

Refer to Figure 115 below for the controls in this section.

Figure 115. The Ambience Recovery controls

Recover Enable This switch enables/disables the ambience recovery process. See "Ambience Recovery" on page 390 for an overview.

Recover Enable must be engaged for the Ambience Gain, Enhance Deep/Wide, and Ambience Filters controls to have an effect.

Note: This switch does not have any effect on the M/S Gain, L/R Gain, or Power controls.

Ambience Gain The Ambience Gain knob controls the level of recovered ambience. The default 0 dB position is defined as the nominal or "typical" setting (ambience recovery is occurring when set to 0 dB).

> Increase or decrease Ambience Gain to change the amount of recovered ambience. The range is -20 dB to +9 dB, available in 0.5 dB steps. Click the "O" label to quickly return to 0 dB. To disable ambience recovery, use the Recover Enable switch.

Note: Values below 0 dB do not remove ambience.

Enhance The ambience recovery process can be manipulated further with the Deep and Wide switches.

Note: The Enhance functions can only be enabled when the Recover switch is engaged.

Deep

Provides deeper ambience recovery when the switch engaged.

Wide

Spreads and enhances the stereo image when the switch is engaged.

Ambience Filters

The Ambience Filters (EQ) provide for frequency adjustments to the ambient portion of the signal. These controls do not affect the direct (dry) portion of the signal.

The Ambience Filters consist of one Low Cut filter, one High Cut filter, and a single-band parametric bell filter.

Note: Controls in the Ambience Filters section have no effect unless the Recover Enable switch is engaged.

Refer to Figure 116 below for the controls in this section.

Figure 116. Ambience Filters controls

EQ Enable The EQ switch enables/disables the Ambience Filters. This switch can only be engaged when the Recover Enable switch is engaged.

Cut Filters The Low Cut and High Cut filters have a slope of 12 dB per octave. Each Cut Filter can be independently disabled by setting it to the OFF position (the default value).

Low Cut

The available range is 20 Hz to 1 kHz.

High Cut

The available range is 5 kHz to 20 kHz.

Bell Filter The bell filter is fully parametric, with independent control of frequency, gain, Q (bandwidth), and gain.

Bell Frequency

This control sets the center frequency of the bell filter. The available range is 150 Hz to 10 kHz.

Bell Q

Bell Q determines the bandwidth of the bell filter. The available range is 0.5 to 3. Smaller Q values cause the bell filter to effect a broader portion of the frequency spectrum, while high Q values affect a narrower spectrum.

Bell Gain

Bell Gain determines how much boost or cut is applied to the bell filter. The available range is ± 10 dB. To quickly return to the 0 dB setting, click the GAIN text label.

Note: The two other Bell parameters (Frequency and Q) have no effect when Bell Gain is set to 0 dB.

Mid/Side Controls

The Mid/Side controls allow for level adjustments to the middle (center) and side portions of signals within a stereo field. Mid/Side adjustments can be made when ambience recovery is active or disabled. Note that the ambience recovery process does not use or require mid/side techniques to achieve ambience recovery or enhancement.

Note: The Mid/Side controls are disabled when the plug-in is used in a mono-in/mono-out configuration.

Refer to Figure 117 below for the controls in this section.

Figure 117. The Mid/Side controls

M/S Gain This switch enables/disables the Mid Gain and Side Gain controls. **Enable**

Mid Gain Mid Gain adjusts the level of signals in the middle of a stereo signal. The available range is -12 dB to +6 dB, available in 0.1 dB steps. To quickly return to the 0 dB setting, click the MID text label.

Side Gain Side Gain adjusts the level of signals at the sides of a stereo signal. The available range is -12 dB to +6 dB, available in 0.1 dB steps. To quickly return to the 0 dB setting, click the SIDE text label.

Output Gain Controls

Refer to Figure 118 below for the controls in this section.

Figure 118. The Output Gain controls

L/R Gain Enable This switch enables/disables the Left/Right Gain and Link controls.

Link This switch links (gangs) the Left/Right Gain controls for ease of operation when both channels require the same value. Disable Link when independent left/right control is desired.

Note: When Link is inactive and Link is engaged, the left gain value is copied to the right gain. Any offset between the gain values is lost.

Left/Right Gain The independent Left and Right Gain have an available range of -24 dB to +12 dB, available in 0.1 dB steps. To quickly return to the 0 dB setting, click the respective LEFT or RIGHT text labels.

Note: The right channel gain control is disabled when the plug-in is used in a mono-in/mono-out configuration.
Output Level Meters

LEFT -30 -27 -24 -21 -18 -15 -12 -9 -6 -3 0 RIGHT -0.6 dB

The stereo peak/hold meters display the signal level at the output of the plugin. The meter range is from -30 dB to 0 dBFS. Signal peaks are held for 3 seconds before resetting.

Power

When the Power switch is in the OFF position, the interface elements do not illuminate, plug-in processing is disabled, and UAD DSP usage is reduced (unless UAD-2 LoadLock is enabled).

Click the switch or the OFF/ON labels to change the setting, or click the UA logo to toggle the setting.

Factory Preset Notes by Bob Katz

Precision K-Stereo includes factory presets designed by Bob Katz for use with his signature plug-in. Descriptions about these presets are listed below.

The Default preset and presets with the "BK" prefix are the settings created by Mr. Katz. Two categories are included: "MIX" presets for use during mixing, and "MSTR" for use during mastering.

Default When Precision K-Stereo is instantiated, it automatically starts with the Default preset, which sets the Ambience Level to 0 dB (a nominal starting point which works well with a lot of music), engages Wide and Deep, and sets everything else to neutral. Feel free to turn the Ambience Level up or down to taste or to explore the possibilities. The rest of the factory presets are provided to demonstrate possibilities, but since there are very few controls, it's easy to get the Precision K-Stereo working for any situation.

- **BK-MSTR-Rock Tight Bass** This preset has Ambience Level at 0 dB, Wide and Deep engaged, and the Ambience Low Cut filter set to 125 Hz to maintain a tight bass instrument while increasing the size and depth of the rest of the instruments.
- **BK-MSTR-Rock Tight Drums** This preset has Ambience Level at 0 dB, Wide and Deep engaged, Ambience Low Cut filter set to 125 Hz, Ambience High Cut Filter set to 10 kHz. This maintains the bass instrument tight (not as affected by the Ambience Level) as well as softens the ambience of the high frequencies to tighten the percussion, but it retains ambience in the midrange to enhance vocals and midrange instruments.
- **BK-MSTR-String** Ensemble This preset has Ambience Level at +1 dB, Wide is disengaged, Deep is engaged. This is very useful, as the name implies, for enhancing the ambience of a small ensemble or solo instrument without stretching it to the extreme sides, maintaining the ensemble's small size but still help its richness and depth. Try this preset during mixing on a stereo-miked solo guitar (instead of a reverb chamber).
- **BK-MSTR-Full** Orchestra A This is the same as the default preset. Turn the Ambience Level up or down to taste. Perhaps add some Ambience EQ to warm up the sound, or add some presence to the ambience, depending on the nature of the reverberation in the original recording.

BK-MSTR-Full Orchestra B	Same as Full Orchestra A, but the high cut filter is set to 10 kHz which softens the high frequency ambience to tighten the percussion.
BK-MSTR-Clear Presence	If the hall or chamber in the original recording is missing some presence, here's a suggestion on what to do.
BK-MSTR-Raise Mid Instruments	This preset subtly raises the Mid level 1 dB above the side level and recovers a bit of the spacious ambience which is commonly lost when the mid/side ra- tio is raised.
BK-MSTR-Warm Ambience	This preset adds overall warmth to the recovery settings.
BK-MIX-Big Steinway	Try this preset on a stereo recording of a piano to enhance the size and body of the instrument without losing its definition. This preset will illustrate how am- bience EQ is very different from direct EQ. Here we turn up the bottom end and lower midrange of the ambience channel. It might turn a six-foot Yamaha into a nine-foot Steinway, so be careful, or maybe that's exactly what you want to do!
BK-MIX-Big	This preset turns up the ambience level a bit to quickly show you the possibil- ities.
BK-MIX-Too Big	This preset turns up the ambience level very far to quickly show you extreme possibilities.

K-Stereo is a trademark of Robert Katz and Digital Domain, Inc.

CHAPTER 39 Precision Limiter

Overview

The Universal Audio Precision Limiter[™] is a single-band, look-ahead, brickwall limiter designed primarily for mastering with program material. The easyto-use Limiter achieves 100% attack within a 1.5ms look-ahead window, which prevents clipping and guarantees zero overshoot performance. Both the attack and release curves are optimized for mastering, which minimizes aliasing.

Since the Precision Limiter is a colorless, transparent mastering limiter–no upsampling is used, nor does the UA Precision Limiter pass audio through any filters–audio remains untouched unless the compressor is working, in which case only gain is affected.

To really be considered a professional limiter, the metering needs to be superb. The Precision Limiter features comprehensive, high-resolution metering and conforms to the Bob Katz "K-System" metering specifications. This metering allows the user to see what is happening to audio with a great deal of accuracy, with simultaneous RMS and Peak metering and adjustable Peak Hold. And since we know how valuable good metering is, the plug-in can also be bypassed and used strictly as a high-resolution meter.

Key features include user-adjustable Release or intelligent Auto Release, which allows for fast recovery-minimizing distortion and pumping-and a unique selectable Mode switch, which allows you to delicately tailor the attack shape and control the "presentation" for different material. Mode A is the default shape, suitable for most material, while Mode B can be particularly useful on minimal and/or acoustic program material, yielding a more subtle touch.

The Precision Limiter is yet another indispensable UAD tool for your audio arsenal.

Precision Limiter Screenshot

Figure 119. The Precision Limiter plug-in window

Controls Overview

Control knobs for the Precision Limiter behave the same way as all UAD plugins. Input, Output, and Release values can be modified with text entry.

The Precision Limiter introduced a new control style for UAD plug-ins. For the Mode, Meter, Scale, and Clear parameters, click the parameter label, the value text, or the LED to toggle between available values.

Precision Limiter Controls

Input	The Input knob controls the signal level that is input into the limiter. Increasing the input will result in more limiting as the input signal exceeds 0 dB.
	The default value is 0 dB. The available range is –6 dB to 24 dB.
Output	The Output knob determines the maximum level at the output of the plug-in. This control does not affect the actual limiting.
	The Precision Limiter always limits the signal to 0 dB internally, and the actual output is set by attenuating this internal level. Likewise, the input control can drive the signal over 0 dB to get more limiting.
	If the Precision Limiter is the last processor in the signal path when mixing down to disk (bouncing), the Output value will be the level of the highest peak in the resultant audio file.
	The default value is –0.10 dB. The available range is from –12 dB to 0 dB. Non-zero values are always negative, therefore during text entry operations positive or negative values may be entered and the result will be negative.

Release	The Release knob sets the value of the limiter release time. The default value is Auto. The available range is from 1 second to 0.01 milliseconds.
	Auto Mode
	When the Release knob is fully clockwise, Automatic mode is active. In Auto mode, release time is program-dependent. Isolated peaks will have a fast re- lease time, while program material will have a slower release.
	Note: You can type "A" or "a" to enter Auto mode during text entry.
Mode	The Mode switch affects the attack shape of the limiter. Subtle tonal variations are possible by switching the Mode between A and B.
	Mode A is the default shape, suitable for most material, while Mode B can be particularly useful on minimal and/or acoustic program material, yielding a more subtle touch.
Power	The Power switch determines whether the plug-in is active. When the Power switch is in the Off position, plug-in processing is disabled and UAD DSP usage is reduced (unless <i>UAD-2 DSP LoadLock</i> is enabled). When the plug-in is bypassed with this switch (but not by the host bypass), the VU meter displays the unprocessed input signal level.

Precision Limiter Meters Overview

K-System The Precision Limiter has precise, calibrated stereo metering. It offers the option to use K-System metering, which is a method devised by renown audio engineer Bob Katz (http://digido.com). The K-System is essentially a method of integrating metering and monitoring levels to standardize the apparent loudness of audio material while providing useful visual feedback of average and peak levels.

Integrated Meter/Monitor System

The K-System is not just a metering system; it is designed to be integrated with calibrated monitoring system levels. In a full K-System implementation, 0 dB on the level meter yields 83 dB sound pressure level (SPL) per channel in the monitor output level (86 dB running two channels in stereo), when measured

with 20-20 kHz pink noise on an SPL meter set to C-weighted slow (i.e. average) response. It is this calibrated meter/monitor relationship that establishes a consistent average "perceived loudness" with reference to 0 dB on the meter.

Sliding Meter Scale

With the K-System, programs with different amounts of dynamic range and headroom can be produced by using a loudness meter with a sliding scale, because the moveable 0 dB point is always tied to the same calibrated monitor SPL. The Precision Limiter provides several meter ranges for various types of program material (see "Type" on page 403).

Long Live Dynamic Range!

The K-System can help combat the bane of the "loudness wars" which is alltoo common in today's music, whereby material is made to appear louder when compared to other material at the same playback volume, at the expense of dynamic range and fidelity.

TypeThe Type switch defines the 0 dB point in the meter scale (see "Sliding Meter
Scale" on page 403). There are three different K-System meter scales, with
0 dB at either 20, 14, or 12 dB below full scale, for typical headroom and
SNR requirements of various program materials.

Each of these modes displays the The RMS and instantaneous peak levels, which follow the signal, and the peak-hold level (see "Meter Response" on page 405).

Figure 120. Precision Limiter Meter Types

K-20

K-20 mode displays 0 dB at –20 dB below full scale. K-20 is intended for material with very wide dynamic range, such as symphonic music and mixing for film for theatre.

K-14

K-14 mode displays 0 dB at –14 dB below full scale. K-14 is intended for the vast majority of moderately-compressed material destined for home listening, such as rock, pop, and folk music.

K-12

K-12 mode displays 0 dB at –12 dB below full scale. K-12 is recommended for material intended for broadcast.

Peak-RMS

This is what is often considered a "normal" digital meter, where 0 dB is full-scale digital code.

	Note: When the meters are in the K-modes, the displayed RMS level is 3.01 dB higher when compared to the same signal level in the Peak-RMS mode. This is done to conform to the AES-17 specification, so that peak and average measurements are referenced to the same decibel value with sine waves.
Meter Response	The main stereo Input/Output meter actually displays three meters simulta- neously: The RMS and instantaneous peak levels, which follow the signal, and the "peak-hold" (also known as global peak) level.
	The peak-hold level is the maximum instantaneous peak within the interval set by the Hold button, and is also displayed as text to the right of the meters. To reset the peak hold levels, press the Clear button.
	Precision Limiter metering is also active when plug-in processing is deacti- vated with the Precision Limiter Power switch. Metering is disabled when the plug-in is bypassed by the host application.
Gain Reduction Meter	The Gain Reduction meter displays the amount of limiter gain reduction. More green bars moving to the left indicate more gain reduction is occurring.
	Gain reduction only occurs when the input signal level exceeds 0 dB. There- fore, increasing the Input knob usually results in more gain reduction.
Meter	The Meter switch specifies the signal source for the main stereo meter, either input or output.
	Input
	When the Meter switch is in Input mode, the main level meters display the sig- nal level at the input of the plug-in (and is not affected by the Input knob).
	Output
	When the Meter switch is in Output mode, the main level meters display the level at the output of the plug-in. When the Limiter is enabled, the Output and Input knobs will affect this display.
Scale	The meter Scale switch increases the resolution of the main stereo level meter (See Figure 121 below). The meter range that is displayed in Normal and Zoom modes is dependent upon the meter Type setting (see "Type" on page 403).

Figure 121. Precision Limiter meter scale in PK-RMS Zoom mode

The main level meters in Normal mode, and the gain reduction meter in both Normal and Zoom modes, are linear (level differences between LED segments is the same). In PK-RMS and K-20 Zoom modes however, the main level meters use two different linear ranges for increased accuracy.

The ranges and response for each meter type and scale is detailed below.

PK-RMS

In Normal mode, the meter range is -60 dB to 0 dB with a linear response of 0.5 dB per segment. In Zoom mode, the range is -18 dB to 0 dB with two different linear responses: 0.2 dB per segment from -18 to -6 dB, and 0.1 dB per segment from -6 to 0 dB.

K-20

In Normal mode, the meter range is -40 dB to 20 dB with a linear response of 0.5 dB per segment. In Zoom mode, the range is -8 dB to 20 dB with two different linear responses: 0.2 dB per segment from -8 to 15 dB, and 0.1 dB per segment from 15 dB to 20 dB.

K-14

In Normal mode, the meter range is -46 dB to 14 dB with a linear response of 0.5 dB per segment. In Zoom mode, the range is -10 dB to 14 dB, with linear response of 0.2 dB per segment.

K-12

In Normal mode, the meter range is -48 dB to 12 dB with a linear response of 0.5 dB per segment. In Zoom mode, the range is -12 dB to 12 dB, with linear response of 0.2 dB per segment.

Hold	The meter Hold Time switch determines how much time will pass before the peak values for the main meter and the gain reduction meter are reset. It affects both the peak LED's and the peak text display.
	Values of 3 seconds, 10 seconds, or Infinite (indicated by the lazy-8 symbol) can be selected.
Clear	The meter Peak Clear switch clears the meter peak value display. It affects both the peak LED's and the peak text display.

Precision Limiter Latency

The Precision Limiter has a 1.5ms look-ahead window to ensure clipping does not occur. This look-ahead function results in a slightly larger latency than other UAD plug-ins. See "Upsampled Plug-Ins" on page 563 for more information.

Note: Compensating for Precision Limiter is not required if the host application supports full plug-in delay compensation throughout the signal path, or when it is used only on the outputs.

CHAPTER 40

Precision Maximizer

Overview

The Precision Maximizer is a dynamic impact processor that uniquely enhances the apparent loudness, warmth, and presence of individual tracks or program material without appreciably reducing dynamic range or peak level control. Significant audio improvements can be achieved without the fatiguing artifacts typically associated with traditional dynamic processors.

The plug-in uses a proprietary soft-saturation process that maximizes signal energy while minimizing undesirable distortion and aliasing. A wide variety of sounds are available using relatively few controls. The primary sonic parameter is the Shape control, which can range from simply increasing the apparent loudness at lower settings, to dramatically improved clarity, punch, and "musical" tube-like distortion at higher values.

The nature of the source material, as well as the input levels to the processor, also greatly affect the sonic character at the output. The Limit function and 3band mode enable further manipulation of signal levels for additional creative options.

Note: See "Operating Tips" on page 413 for practical usage information.

Signal Flow The input signal first passes through the Input control (page 409), then the Input Meter (page 409), before arriving at the Bands divider (page 410). After being optionally divided by the Bands parameter, the signal is then split into the dry path and the wet saturation path. The saturation path is processed by the Shape control (page 410), then the wet and dry signals are combined with the Mix control (page 411). Finally, the mixed signal is processed by the Limit control (page 411) before being passed to the Output control (page 412) and Output Meter (page 412).

Precision Maximizer Screenshot

Figure 122. The Precision Maximizer plug-in window

Precision Maximizer Controls

Control knobs for the Precision Maximizer behave the same way as all UAD plug-ins. Input, Shape, Mix, and Output values can be modified with text entry.

Input Meter

The stereo peak Input Meter displays the signal level at the input of the processor, after the Input control.

0 dB represents digital full scale (0 dBFS). Precision Maximizer can utilize input signals up to +6 dB at the input before input clipping occurs.

The displayed range is from –40 dB to +6 dB.

Input

The Input Level knob controls the signal level that is input to the plug-in. Increasing the input will generally result in more processing (depending on the settings of the other parameters).

By increasing the Input knob, input levels higher than O dBFS (up to +6 dBFS) within the plug-in can be processed. This can increase the distortion characteristic at

the output, particularly when the Limit function ("Limit" on page 411) is engaged.

The available range is ± 12 dB. A good starting point for sonic experimentation is to set the input level so the input peaks occur around 0 dB, then adjust the other controls to taste.

Shape

The Shape knob is the primary saturation control for the Maximizer effect. It contours the harmonic content and apparent dynamic range of the processor by changing the small-signal gain of the saturator. The available range is 0–100%.

At lower settings, apparent loudness is not as dramatic but harmonic processing still occurs, producing a richer sound

with minimal reduction of dynamic range. As Shape is increased, the sound becomes more saturated with "sonically pleasing" distortion and perceived loudness, punch, and clarity.

Shape values between 0-50% will make the effect more subtle, but a richer sound is still obtained. Lower Shape values accentuate louder peaks, which can sound great on percussive instruments. Solo instruments can also benefit from lower Shape values by taming the peaks while maintaining dynamic range.

As Shape is increased beyond 50%, presence, excitement, and harmonic coloration can be dramatic, yet still highly musical and without the dynamic squashing of typical limiters.

The most natural warmth and tube-like distortion is obtained with Shape at 50%. This setting generates the lowest amount of higher order harmonics and most closely emulates characteristic tube qualities.

Bands

Precision Maximizer can operate in one-band or three-band mode. In one-band mode, all frequencies are processed equally. In threeband mode, the frequency spectrum is split into three separate bands before maximizing is applied.

One-band mode is the normal setting for general usage. In this mode, more dramatic results can often be obtained because more saturation effect is possible before the output is clipped. At higher levels of distortion, the phase of the harmonics are also better retained in this mode, which usually produces a more desirable sound quality.

Higher levels of perceived loudness may be obtained in three-band mode, especially if the frequency spectrum of the source material is not balanced. In this mode, certain settings can produce higher output levels than input levels (and potential clipping), so it may be necessary to compensate by reducing the input/output levels, and/or engaging the Limit control.

The crossover frequencies in three-band mode are 200 Hz and 2.45 kHz.

Click the Bands button to change the mode. Alternately, you can click+hold the LED area and drag like a slider to change the value.

Note: UAD DSP usage is increased when three-band mode is active (unless UAD-2 DSP LoadLock is enabled).

Limit

The Limit function provides a second stage of soft-saturation just before the output control for the plug-in. It prevents digital "overs" by protecting the plug-in output from exceeding 0 dBFS. Limit enters into clipping range gradually instead of hard-clipping at 0 dB.

The Limit function has the same saturation form as the Shape parameter, but the effect is milder. Limit is especially useful for three-band mode, where output peaks over 0 dB (and clipping) can occur. However, great results can also be obtained in one-band mode when Limit is engaged.

If Limit is used to reduce levels by a significant amount, it is usually best to have Mix set to 100% in order to minimize audio artifacts (aliasing).

Click the Limit button to engage Limit. Alternately, you can click+hold the LED area and drag like a slider to change the value.

Note: UAD DSP usage is slightly decreased when Limit mode is inactive (unless UAD-2 DSP LoadLock is enabled).

Mix

The Mix knob is a mix control for the plug-in. Mix determines the balance between the original and the processed signal.

The range is from 0% (no processing) to 100% (wet, processed signal only).

Note that when Mix is at 0%, the signal is still processed by the Limit control if it is enabled, and by the band splitter when in three-band mode. For a true bypass, the Power switch should be used.

Output

The Output knob controls the signal level that is output from the plug-in. The available range is -12 dB to 0 dB.

Note that when Limit is not engaged, it is possible for the output level to exceed 0 dB. In this case, Output can be lowered to eliminate any associated clipping.

When Precision Maximizer is used for CD mastering and it is the last processor in the signal chain, the recommended Output value is -0.10 dB

Output Meter

The stereo peak Output Meter displays the signal level at the output of the plug-in. The displayed range is from -40 dB to 0 dB.

The very top segment of the Output Meter is a clip LED (one each for the left and right channels) which illuminates when the signal exceeds 0 dB. The clip segments are held for three seconds before resetting.

Note: The Limit function prevents the output signal from exceeding O dB. Therefore, the clip LED's will only illuminate if Limit is off.

The Power switch determines whether the plug-in is active. This is useful for comparing the processed settings to the original signal or bypassing the plug-in to reduce the UAD DSP load (load is not reduced if UAD-2 DSP Load-Lock is enabled).

Toggle the switch to change the Power state; the UA logo is illuminated in blue when the plug-in is active.

Note: You can click-hold the power switch then drag it like a slider to quickly compare the enabled/disabled state.

Operating Tips

- As a starting point for general loudness enhancement, set Precision Maximizer to one-band mode with Limit engaged, with Mix at 100% and Shape at 50%. Then set Input so signals peak at around 0 dB on the Input Meters. These settings offer good results under most conditions, producing more presence with a warmer sound and enhanced detail (especially with lower frequencies), while retaining the apparent dynamic range of the original signal.
- The most natural warmth and tube-style distortion can be obtained with Shape at 50% in one-band mode, with Limit off, and signal peaks just touching 0 dB at the input. Shape at 50% delivers the lowest amount of higher order harmonics and most closely emulates a tube characteristic.
- More overdrive may be obtained by disengaging the Limit function. Up to +6 dB of additional headroom is available before clipping occurs when Limit is off. This can cause clipping at the output, so reduce the Input and/or Output control to compensate if necessary.
- Input clipping can dramatically change the distortion characteristic, and may yield significantly different results in one-band versus three-band mode.
- Generally speaking, the input should be set as high as possible before undesirable sound quality is obtained.
- For optimum results (especially when Limit is off) ensure the source signal is not clipped before it arrives at the Precision Maximizer input.
- Output clipping can be completely avoided by enabling Limit.
- One-band mode is generally recommended for program material.
- Set Mix at 100% in order to hear the full affect of the Maximizer process. Reduce Mix when blending in the original signal is desired.
- Changing the order of plug-ins in the signal path can have a dramatic affect on Precision Maximizer results.
- Sonic experimentation is highly encouraged!

Precision Maximizer Latency

The Precision Maximizer uses an internal upsampling technique. This upsampling results in a slightly larger latency than other UAD plug-ins. See See "Upsampled Plug-Ins" on page 563. for more information.

CHAPTER 41

Precision Multiband

Overview

The Precision Multiband is a specialized mastering tool that provides five spectral bands of dynamic range control. Compression, expansion or gate can be chosen separately for each of the five bands. The unparalleled flexibility and easy to follow graphical design of the Precision Multiband make it the ideal tool for the novice as well as the seasoned mastering engineer.

The Precision Multiband can be used for anything from complex dynamic control to simple de-essing. Two filter bank modes offer precise linear-phase or minimum-phase gain control; use the linear-phase option for perfectly phasecoherent results, or minimum-phase for a more "analog" sound. Both filter bank modes achieve the magnitude response of a Linkwitz-Riley filter and provide perfect magnitude reconstruction.

Precision Multiband Screenshot

Figure 123. The UAD Precision Multiband plug-in window

Precision Multiband Interface

The Precision Multiband interface is designed to make this complex processor easier to use.

Five separate frequency bands are available for processing. Each band is identified by a unique color, and all controls specific to the band have the same color. This helps to visually associate parameters to the band that they affect. The band names and their colors are:

- Low Frequency (LF): Red
- Low-Mid Frequency (LMF): Orange
- Mid Frequency (MF): Yellow
- High-Mid Frequency (HMF): Green
- High Frequency (HF): Blue

The interface is divided into four primary areas of control:

- The Band Controls section contains the dynamic response parameters for each of the five bands. One set of band controls is displayed at a time. See "Band Controls" on page 416.
- The EQ Display contains the band frequency parameters and shows a graphic representation of the band frequency response. The overall equalization response is also displayed (if enabled). See "EQ Display" on page 421.
- The Dynamics Meters display the amount of gain reduction or expansion occurring on each band. The band enable and solo controls are here also. See "Dynamics Meters" on page 424.
- The Global controls affect aspects of the plug-in not associated with individual bands. These include input/output controls and meters, power, and other controls. See "Global Controls" on page 425.

Band Controls

The Band Controls contain the parameters that are used to specify all the settings for each band (except the frequencies; see "Frequency Controls" on page 423).

The Band Controls for each of the five bands are identical.

Only one set of Band Controls is displayed at a time. The control set for any particular band is displayed by selecting the band (see "Band Select" on page 416).

Band Select Selecting a band causes the controls for that band to be displayed in the Band Controls area. Bands can be selected by using the Band Select buttons, or by clicking in the EQ display.

Band Select Buttons

The Band Select buttons at the top of the EQ Display specify which band parameters are displayed in the band controls section. Click the button to display the parameters for the band.

EQ Display Selection

A band can also be selected by clicking within the area of the band in the EQ Display. For example, clicking within the area shown here will select the LMF band.

Band Parameters

Because the Band Controls for each of the five bands are identical, they are only described once.

All Button

The ALL button provides a facility to link controls and copy parameter values to all bands when adjusting the current band. Each of the Band Controls has an ALL button. The behavior of the ALL button is the same for all the Band Controls in all the bands (with the exception of the Type switch; see "Type Switch" on page 418)

The ALL button can perform three functions: Relative Link, Absolute Link, and Copy Value. Note that the ALL button cannot be automated.

Relative Link

In Relative mode, changes to a band control will change the same control in the other bands by a relative amount (i.e. the same amount), until any single band reaches its minimum or maximum value.

Single-click the ALL button to enter Relative mode; the button background changes to blue.

When adjusting a control in Relative mode, it may appear that the full range of the active control is unavailable; this occurs when a different band (not the active band) has reached the end of its range.

In Relative mode the Gain value can also be adjusted by dragging the Gain "handle" in the EQ Display (see "EQ Display" on page 421).

Note: No change occurs to the parameter values unless the control is actually moved. This allows you turn off relative linking without making any changes.

Note: Relative mode is not available for the Type parameter because the available Type values are discrete. Click and shift-click both activate Absolute mode for Type.

Absolute Link

ALL

In Absolute mode, changes to a band control will force the same control in the other bands to snap to the same value as the current band.

Shift-click the ALL button to enter Absolute mode; the button background changes to red.

In Absolute mode the Gain value can also be adjusted by dragging the Gain "handle" in the EQ Display (see "EQ Display" on page 421).

Note: No change occurs to the parameter values unless the control is actually moved. This allows you turn off absolute linking without making any changes.

Сору

Ctrl-click the ALL button when it is NOT in Relative or Absolute modes (not blue or red) to copy the current value of the active band control to the same control value in the other bands.

Note: Careful with the control Copy function! It will delete the existing values in the other bands, and no undo is available.

Type Switch

The Type button defines the dynamic nature of the band, allowing each band to function as a compressor, expander, or noise gate, independent of the Type value in the other bands.

Click the Type switch to scroll through the three available values.

The Type text (compress, expand, gate) behaves as a vertical "slider" and can be used for changing the Type as well. Alternately, the Type can be changed using the Dynamics Meters label text (see "Dynamics Meters" on page 424).

Note: When changing the band Type, the Ratio value for the band changes to 1:1. This prevents dramatic jumps in the output level that could result from extreme values of other band parameters.

COMPRESS

When a band is set to Compress, the dynamic range of the band will be reduced (dependent upon the band threshold and input level). This is the typical value in multiband compression.

EXPAND

When a band is set to Expand, the dynamic range of the band will be increased (dependent upon the band threshold and input level).

GATE

When a band is set to Gate, the band behaves as a gate. A gate stops the signal from passing when the signal level drops below the specified threshold value.

Gates are generally used to reduce noise levels by eliminating the noise floor when the 'main' signal is not present, but they are also useful for special effects.

Threshold This parameter determines the threshold level for compression/expansion/gating. Any signals that exceed this level are processed. Signals below the level are unaffected. A Threshold of 0 dB yields no processing. The available range is -60 dB to 0 dB.

As the Threshold control is decreased and more processing occurs, output level is typically reduced (compression) or increased (expansion). Adjust the Gain control to modify the output of the band to compensate if desired.

Ratio Ratio determines the amount of gain reduction (or expansion) for the band. For example: When a band is set to Compress, a value of 2 (expressed as a 2:1 ratio) reduces the signal by half, with an input signal of 20 dB being reduced to 10 dB.

The available range depends on the value of the Type parameter, as follows:

- Ratio range in Compress mode is 1:1 to 60:1
- Ratio range in Expand mode is 1:1 to 1:4
- Ratio range in Gate mode is 1:1 to 8:1

Attack	Attack sets the amount of time that must elapse once the input signal reaches the Threshold level before processing is applied. The faster the Attack, the more rapidly processing is applied to signals above the threshold.
	The available range is 50 microseconds to 100 milliseconds.
Release	Release sets the amount of time it takes for processing to cease once the input signal drops below the threshold level. Slower release times can smooth the transition that occurs when the signal dips below the threshold, especially useful for material with frequent peaks. However, if you set too large of a Release time, processing for sections of audio with loud signals may extend to lengthy sections of audio with lower signals. The available range is 20 milliseconds to 2 seconds.
Gain	The Gain control adjusts the output level of the band. Generally speaking, adjust the Gain control <i>after</i> the desired amount of processing is achieved with the Threshold control. The Gain control does not affect the amount of processing. The available range is ± 12 dB.
	Note: The Gain for each band can also be modified by control points in the EQ Display (see "Curve Control Points" on page 421).
Band Frequencies	For details about the band frequencies, see "Frequency Controls" on page 423.
Band Enable & Solo	For details about the band enable and solo controls, see "Dynamics Meters" on page 424.

EQ Display

In the EQ Display, the entire audio spectrum from 20 Hz to 20 kHz is displayed along the horizontal axis. Gain and attenuation of the five band frequencies (up to ± 12 dB) are displayed along the vertical axis.

Figure 124. Precision Multiband EQ Display

Band Curves The Band Curves show the relative frequency and gain settings of the bands. The sides of the colored curves are a representation of each band's frequency settings, and the top of each curve represents the band's gain setting.

Note: The currently selected band is displayed with a thicker bold line. Disabled bands (see "Band Enable & Solo" on page 420) are displayed with a thinner line.

- **EQ Response** The EQ Display also shows the processed EQ response dynamically as a light blue line across all bands (if the Dynamic EQ display option is enabled; see "EQ Display Switch" on page 426).
- **Curve Control Points** Band gain, center frequencies (cF), crossover frequencies (xF), and bandwidth can be modified by manipulating the colored band curves in the EQ Display with the cursor.

When the cursor is moved over the pre-defined "hot spots" in the EQ Display, the cursor changes shape to indicate that adjustments can be made. Each of these control points and their corresponding available adjustments are detailed below.

Adjusting Gain

The gain of a band can be adjusted by click-dragging the top of its colored line. In this case the cursor changes to an up/down arrow when hovered over the hot spot to indicate the direction available for dragging.

Adjusting Gain and cF

If the cursor is moved slightly lower than the above example, the gain and center frequency can be adjusted simultaneously, without adjusting the bandwidth. In this case the cursor changes to an up/down/left/right arrow when hovered over the hot spot to indicate the direction available for dragging.

Adjusting Gain and Bandwidth

If the cursor is moved to the upper-left region of the three center bands (LMF, MF, HMF), the gain and bandwidth can be adjusted simultaneously, without changing the center frequency. In this case the cursor changes to a diagonal arrow when hovered over the hot spot to indicate the direction available for dragging.

Adjusting xF

If the cursor is moved to where two bands crossover, the crossover frequencies can be adjusted, without changing the gain or center frequency. In this case the cursor changes to a left/right arrow when hovered over the hot spot to indicate the direction available for dragging.

Note: Frequencies can also be adjusted by using the Frequency Value parameters (see "Frequency Values" on page 423).

Frequency Controls

The crossover frequency (xF) between the bands and the center frequency (cF) of the Mid bands is shown at the bottom of the EQ Display (see "EQ Display" on page 421).

The frequencies for each band can be modified by entering the values directly and by manipulating the colored band curves.

Frequency Values

All band frequency values are always displayed. Values can be input directly using text entry.

If a value is entered that is outside of the minimum and maximum allowable value, the entry field will not accept the change and the value for the entry field will remain unchanged.

For the center frequencies, if a value is entered that is still within the acceptable min/max range but the center frequency can not reach the input value because it would require a change to the width, then the nearest allowable value is set. If a lower or greater center frequency value is desired (i.e., the original center frequency value attempt), the width of the band must be reduced first, then the center frequency adjusted again. It's easiest to see the cF limits at the given width by dragging the center frequency with the mouse.

To modify the frequency (and gain) values using the EQ Display, see "Curve Control Points" on page 421).

Dynamics Meters

Realtime display of Precision Multiband dynamics processing is shown in the Dynamics Meters. This area also contains the band enable and band solo controls.

There is one vertical dynamics meter for each band. They are color coded to match the bands, and represent (from left to right) the LF, LMF, MF, HMF, and HF bands respectively. Dynamics processing for each band is indicated by light blue "LED-style" metering.

Zero dB is at the center of the meter, and the range is ± 15 dB. Downward/negative metering indicates compression is occurring on the band. Upward/positive metering indicates expansion is occurring.

In Gate mode, there is simultaneous inward metering from the top and bottom to the center, which provides a visual "gate" that opens and closes along with the gate processing.

Dynamics Meters signal peaks are held for 3 seconds before resetting.

Meter Labels	The labels above the Dynamics Meters reflect the mode that each band is in: GR (Gain Re- duction) for compression, EXP for expansion, and GT for Gate.
Band Enable Buttons	Each band has an Enable button. The Enable button for the band is just below its dynamics meter. The band is active when its Enable button is light blue. Click the button to toggle the active state of the band. Disabling bands
Paud Sala	does not reduce UAD CPU usage.
Buttons	the band is just below its Enable button.

heard and the other bands are muted.

The band is soloed when its Solo button is red. Click the button to toggle the solo state of the band. Soloing bands does not reduce UAD CPU usage.

Solo Display

When a band is in Solo mode, its curve in the EQ Display is highlighted.

Note: In addition to the Solo buttons, you can also control-click a band in the EQ Display to put any band (or bands) into Solo mode.

Global Controls

- Input Level Meter
 - peak/hold Input Meter displays the signal level at the input of the plug-in. Signal

The stereo

peaks are held for 3 seconds before resetting.

- **Input Level Knob** The Input Level knob controls the signal level that is input to the plug-in. Increasing the input may result in more processing, depending on the values of the band parameters. The default value is 0 dB. The available range is ± 20 dB.
- **Mix** The Mix control determines the balance between the original and the processed signal. The range is from 0% (no dynamics processing) to 100% (wet, processed signal only). The default value is 100%.

Note that at 0% the signal is still being processed by the band

splitter in the plug-in. In linear phase mode the splitter is inaudible, but in minimum phase mode you may hear a slight coloration of the signal at 0%.

Output Level Meter	The stereo peak/hold Out- put Meter dis- plays the signal level at the output of the plug-in. Signal peaks are held for 3 seconds before resetting.
Output Level Knob	The Output Level knob controls the signal level that is output from the plug-in. The default value is 0 dB. The available range is ±20 dB.
EQ Display Switch	The EQ Display mode can be static or dynamic. The EQ Display switch deter- mines the active mode. Click the switch to toggle the mode.
	EQ
	In this mode, the EQ Display is static. Only the colored frequency bands are displayed.
	Dynamic EQ
	In Dynamic EQ mode, a light blue line in the EQ Display indicates the actual frequency response of the processor in realtime.
Phase Mode Switch	The filter bank mode of Precision Multiband can be specified with the Phase Mode switch. Click the switch to toggle the mode. The default mode is Linear.
	Both filter bank modes achieve the magnitude response of a Linkwitz-Riley fil- ter and provide perfect magnitude reconstruction.
	Linear
	Use linear phase mode when perfectly phase-coherent results are desired.
	Minimum
	Minimum phase mode provides a more "analog" (i.e., colored) sound and uses slightly less UAD CPU.
	While the DSP savings are rather negligible, there is a functional advantage to Min phase mode. When Precision Multiband is used as a track compres- sor, Min phase mode provides the advantage of rapid response time of the fil- ters for smooth automation and filter sweeps.

Power Switch The Power Switch determines whether the plug-in is active. Click the toggle button or the UA logo to change the state.

When the Power switch is in the Off position, plug-in processing is disabled and UAD DSP usage is reduced (unless *UAD-2 DSP LoadLock* is enabled).

When the plug-in is bypassed with this switch (but not by the host bypass), the I/O meters and the Input Level knob remain active.

Precision Multiband Latency

The Precision Multiband requires a large processing buffer to perform its sonic wonders. This buffer results in a significantly larger latency than other UAD plug-ins, including all other upsampled plug-ins. You may use Delay-Comp or TrackAdv to compensate. See See "Upsampled Plug-Ins" on page 563. for more information.

Important: Compensating for Precision Multiband latency is not required if the host application supports full plug-in delay compensation throughout the entire signal path, or when it is used only on the outputs.

CHAPTER 42 Pultec Passive EQ Collection

Introduction

The Pultec Passive EQ Collection is the final word in fastidious circuit reproduction of Pulse Techniques' revered passive EQs, considered to be the most popular outboard studio equalizers ever made. With the UAD-2's increased DSP power and ten years of UA's technological advancements since the original Pultec and Pultec-Pro plug-ins, UA has revisited the Pultec family. Maintaining the spot-on filter fits and all-important EQ band interactions, the Pultec Passive EQ Collection expands on sonic detail by modeling the overbuilt transformers and complex tube amplifiers of these must-have production tools. The sophisticated technology used in this new plug-in collection captures all of these tone-enhancing characteristics for individual sources to full program material.

Pultec Passive EQ Collection Screenshots

Figure 125. The Pultec EQP-1A plug-in window

Figure 126. The Pulteq MEQ-5 plug-in window

Figure 127. The Pultec HLF-3C plug-in window

Figure 128. The Pultec-Pro Legacy plug-in window, which includes both the original EQP-1A and the original MEQ-5

Pultec Plug-In Family

The complete Pultec family is comprised of five individual plug-ins, as seen on the previous page. Each variation has its own unique sonic characteristics.

Pultec Passive
EQ CollectionThe Pultec Passive EQ Collection (introduced in UAD v7.1) provides access to
three historical and highly coveted revisions in the Pultec product line.

The plug-ins in the Pultec Passive EQ Collection benefit from the additional processing power afforded by the UAD-2, plus more than 10 years of UA's evolving sophistication designing plug-ins. While the original EQP-1A Legacy and Pultec-Pro Legacy plug-ins remain an excellent rendition of the hardware, the plug-ins in the newer Pultec Passive EQ Collection add the transformer and complex tube amplifier nonlinearities for even more authenticity. The sophisticated modeling technology used in the newer plug-in collection captures all of these tone-enhancing characteristics.

Pultec EQP-1A

Used on a myriad of recordings from the 1950's to today, the three-band, tube-amplified EQP-1A Program Equalizer has long been a studio staple of recording and mix engineers for its ability to bring out individual frequency ranges without significantly altering neighboring frequencies. This unit is equally famous for its ability to dial in seemingly dangerous amounts of boost and famously smooth-as-silk vintage tone. The EQP-1A is also known as the quintessential "magic" studio piece that makes audio simply sound better just by passing through it.

Pultec MEQ-5

The Pultec MEQ-5 Mid-Range Equalizer is the richly colorful tube-amplified companion piece to the EQP-1A. With two bands of midrange boost and one band of midrange dip, the MEQ-5 is designed to enhance and control the "power region" where sound energy is often concentrated, covering the finer tone requirements in the Pultec Collection with an abundance of band overlap and filter interaction.

Pultec HLF-3C

The HLF-3C completes the Pultec Passive EQ Collection. This plug-in has 12 dB per octave low and high cut filters, providing broad retro-tonal sculpting or bygone-era special effects, without the inconvenience of insertion loss found with the unamplified passive hardware. **Pultec Legacy** The Pultec EQP-1A Legacy and Pultec-Pro Legacy plug-ins (Figure 128 on page 429) are the original versions of our Pultec emulations that run on both UAD-1 and UAD-2 devices. They still have a great sound and are very usable, especially when there are not enough DSP resources to use the second-generation versions in the newer Pultec Passive EQ Collection.

To accommodate the limited DSP resources of the original UAD-1, the transformer and I/O distortion characteristics were not modeled in these plug-ins. This makes these legacy versions especially useful in situations where less distortion, and less DSP usage, is desirable.

Operational Overview

The Pultec EQP-1A/MEQ-5 combination is still standard fare in recording studios and was once widely used in mastering sessions. Whether used independently or together, mono or stereo, the Pultec Collection provides a complete vintage EQ palette for individual sources such as bass or kick drums, subgroups such rhythm, horn or string sections, or on the master bus. The EQP-1A's 16 KCS high frequency setting is famous for adding "air" to master sources.

Although unintended by its designers, the Pultec EQP-1A is coveted for its unique ability to boost and cut the same low frequency simultaneously, creating a tightening effect as a naturally interactive resonant dip near the selected frequency. This has the sonic effect of simultaneously tightening and boosting bass frequencies. Select the bass frequency then adjust the balance of Boost and Cut to tune the effect.

- **EQP-1A** Insertion Boost The original EQP-1A hardware unit has an inherent level boost of approximately 1.13 dB when it is in the signal path. This inherent boost is present in the EQP-1A plug-in models as well.
- **Frequency Conventions** The original Pultec hardware used frequency unit names that were conventional before the frequency unit of "Hertz" was widely adopted. The UAD Pultec plug-ins adopt the original frequency unit name conventions.

"CPS" is an acronym for Cycles Per Second, which is now more commonly referred to as Hertz and abbreviated as Hz. KCS is an acronym for KiloCycles per Second, which is now more commonly referred to as KiloHertz and abbreviated as kHz. Artist Presets The Pultec Passive EQ Collection includes artist presets from prominent Pultec users. Some of the artist presets are in the internal factory bank and are accessed via the host application's preset menu. Additional artist presets are copied to disk by the UAD installer so they can be used within Apollo's Console application. The additional presets can be loaded using the Settings menu in the UAD Toolbar (see "Using UAD Powered Plug-Ins" in Chapter 7 of the UAD System Manual).

Note: Presets created with the original Legacy plug-ins are incompatible with the equivalent newer model plug-ins.

Upsampling All UAD Pultec plug-ins use an internal upsampling technique. The upsampling results in a slightly larger latency than other UAD plug-ins. See See "Upsampled Plug-Ins" on page 563. for more information.

Pultec EQP-1A Controls

ControlThe EQP-1A can control three frequency bands simultaneously, using three
groups of interacting parameters.

The first group adjusts the low frequencies and has three controls: boost, attenuation, and frequency select. The second group adjusts the high frequencies and has three controls: boost, bandwidth, and frequency select. The third group also adjusts the highs and has two controls: attenuation amount and frequency select.

The placement and grouping of the sections and their related controls are shown in Figure 129.

Figure 129. Control grouping within the Pultec EQP-1A
EQ Enable

This is the EQ enable control. Like the original hardware, the signal is still colored even when this switch is in the out (down) position, because the signal is still passing through the I/O circuitry. If a true bypass is desired, use the Bypass/Gain knob.

The function of this control differs between the newer EQP-1A and the Legacy version, as described below.

Pultec EQP-1A

This dual purpose knob is an output gain control, and the plugin bypass control. The available output gain range is ± 12 dB.

Rotate the control fully counter-clockwise to disable plug-in processing and reduce UAD DSP load (DSP load is not reduced if UAD-2 DSP LoadLock is enabled).

Tip: Click the "OFF" text label or the red power lamp to toggle between by pass and the previous value.

Tip: Click the "O" text label to set the gain to O dB.

Pultec EQP-1A Legacy

This is the plug-in bypass control. The knob can be used to compare the processed settings to that of the original signal, or to disable the plug-in to reduce UAD DSP load (DSP load is not reduced if UAD-2 DSP LoadLock is enabled).

Note: Output gain is unavailable on the Pultec EQP-1A Legacy plug-in.

Low Frequency Low Frequency Controls

This switch determines the frequency of the low shelf portion of the equalizer. Four frequencies are available: 20, 30, 60, and 100 CPS.

Tip: To cycle through the available values, click the "CPS" text label, or shift+click the text label to cycle through available values in reverse. This function is unavailable with the Legacy version of the plug-in.

LF Boost

This knob determines the amount of low shelf gain to be applied to the frequency set by the CPS switch.

LF Attenuation

This knob ("ATTEN") determines the amount of low shelf cut to be applied to the frequency set by the CPS switch.

Background

In the documentation supplied with hardware version of the EQP-1A, it is recommended that both Boost and Attenuation not be applied simultaneously because in theory, they would cancel each other out. In actual use however, the Boost control has slightly higher gain than the Attenuation has cut, and the frequencies they affect are slightly different too. The EQ curve that results when boost and attenuation are simultaneously applied to the low shelf is an additional feature.

High Boost Controls

High Frequency

This switch determines the frequency of the high boost portion of the equalizer. Seven frequencies are available: 3, 4, 5, 8, 10, 12, and 16 KCS.

Tip: To cycle through the available values, click the "KCS" text label, or shift+click the text label to cycle through available values in reverse. These shortcuts are unavailable with the Legacy version of the plug-in.

HF Q

This knob sets the proportion of frequencies surrounding the center frequency (determined by the KCS switch) to be affected by the high boost (this is a bandwidth control). Lower values yield a narrower band and effect fewer frequencies.

HIGH FREQUENCY

HF Boost

This knob controls sets the amount of gain for the high frequency portion of the equalizer.

High Attonuction	HF Attenuation Frequency	
Controls	This switch ("ATTEN SEL") determines the frequency of the high fre- quency attenuator. Three frequencies are available: 5, 10, and 20 KCS.	ATTEN SEL

Tip: To cycle through the available values, click the "ATTEN SEL" text label, or shift+click the text label to cycle through available

values in reverse. These shortcuts are unavailable with the Legacy version of the plug-in.

HF Attenuation

This knob ("ATTEN") determines the amount of high shelf cut to be applied to the frequency set by the Attenuation Selector switch.

Pultec MEQ-5 Controls

The MEQ-5 can control three frequency bands simultaneously, using three groups of interacting parameters.

The first group adjusts the low-mid frequencies and has two controls: frequency select and boost. The second group adjusts the mid frequencies and has two controls: frequency select and attenuation. The third group adjusts high-mids and has two controls: frequency select and boost. The placement and grouping of the sections and their related controls are shown in Figure 130.

Figure 130. Control grouping within the Pultec MEQ-5

EQ Enable

This is the EQ enable control. Like the original hardware, the signal is still colored even when this switch is in the out (down) position, because the signal is still passing through the I/O circuitry. If a true bypass is desired, use the Bypass/Gain knob (MEQ-5) or the Enable switch (Pultec-Pro Legacy; see page 433).

Low Peak Controls

LM Frequency

This switch determines the frequency of the low-midrange portion of the equalizer. Five frequencies are available: 200, 300, 500, 700, and 1000 CPS.

Tip: To cycle through the available values, click the "PEAK" text label, or shift+click the text label to cycle through avail-

able values in reverse. These shortcuts are unavailable with the Legacy version of the plug-in.

LM Boost

This knob determines the amount of low-midrange gain to be applied to the frequency set by the low-midrange frequency selector.

Dip Controls

Mid Frequency

This switch determines the frequency of the midrange portion of the equalizer. Eleven frequencies are available: 200 CPS, 300 CPS, 500 CPS, 700 CPS, 1 KCS, 1.5 KCS, 2 KCS, 3 KCS, 4 KCS, 5 KCS, and 7 KCS.

Tip: To cycle through the available values, click the "DIP" text label, or shift+click the text label to cycle through available values in reverse. These shortcuts are unavailable with the Legacy version of the plug-in.

Mid Dip

This knob determines the amount of midrange cut (attenuation) to be applied to the frequency set by the midrange frequency selector.

		- 1

This knob determines the amount of high-midrange gain to be applied to the frequency set by the high-mid frequency selector.

verse. These shortcuts are unavailable with the Legacy version of the plug-in.

Bypass/Gain

HM Boost

This is dual purpose knob is an output gain control, and a plug-in bypass control. The available output gain range is ± 12 dB.

Tip: To cycle through the available values, click the "PEAK"

Rotate the control fully counter-clockwise to bypass plug-in processing and reduce UAD DSP load (DSP load is not reduced if UAD-2 DSP LoadLock is enabled).

Tip: Click the "OFF" text label or the red power lamp to toggle between bypass and the previous value.

Tip: Click the "0" text label to set the gain to 0 dB.

Pultec HLF-3C Controls

Unity Gain The Pultec HLF-3C hardware unit is a true passive design; there are no input/output amplifiers and it does not require any external power. As a result, there is an inherent loss of signal level when using the HLF-3C hardware.

> The Pultec HLF-3C plug-in compensates for this inherent signal loss for simplified use in the modern era; it has unity gain upon insertion (there is no insertion loss until one or both of the cut filters is engaged).

High Peak Controls

HM Frequency

portion of the equalizer. Five frequencies are available: 1.5, 2, 3, 4, and 5 KCS.

CPS 150 250 500 100 750 10 80 1000 50 1500 15 OF 2000 OFF 1.5 LOW CUT-OFF HIGH CUT-OFF PHI TEC FILTER HIE-3

Figure 131. The Pultec HLF-3C controls

Enable This toggle switch is the plug-in bypass control. When in the down position (bypassed), plug-in processing is disabled altogether. The plug-in is engaged with the switch is in the up position.

This switch can be used to compare the processed settings to that of the original signal, or to bypass plug-in processing to reduce UAD DSP load (DSP load is not reduced if UAD-2 DSP LoadLock is enabled).

Note: The behavior of this toggle switch differs from the other UAD Pultec plug-ins. Because the HLF-3C hardware is not internally amplified, there is no I/O circuitry modeling to maintain when the EQ portion of the circuit is by-passed (the entire hardware unit is the EQ portion).

Low Cut This rotary switch specifies the cutoff frequency of the low cut filter. Eleven frequencies are available: 50, 80, 100, 150, 250, 500, 750, 1000, 1500, and 2000 CPS.

Tip: To cycle through the available values, click the "CPS" text label, or shift+click the text label to cycle through available values in reverse.

High Cut This rotary switch specifies the cutoff frequency of the high cut filter. Eleven frequencies are available: 1.5, 2, 3, 4, 5, 6, 8, 10, 12, and 15 KCS.

Tip: To cycle through the available values, click the "KCS" text label, or shift+click the text label to cycle through available values in reverse.

History

In 1951, Pulse Techniques introduced the first passive Program Equalizer, the EQP-1. The passive EQ filter designs were originally licensed from Western Electric. Founders Ollie Summerland and Gene Shenk made up the Teaneck, New Jersey operation of Pultec. These two men comprised the engineering, marketing, sales and production staff for the entire history of the company, and made every item to order, all by hand. With the EQP-1A, Pultec improved the original design with tube amplification to overcome the typical insertion loss of passive equalizers. The EQP family of EQs would see many iterations, but the fundamental design would be Pultec's flagship product until the company's closure in the early 80s.

The Pultec Passive EQ Collection Original Hardware

Raw Distortion

A Classic Grinding Distortion

Equal parts warm overdrive and raunchy grind, the Pro Co Rat distortion pedal has been a vital cog in countless guitar rigs since the late '70s. From Jeff Beck to John Scofield, Thom Yorke to Graham Coxon, players of all stripes revere the Rat's tonal range, smoothness, and heaping amounts of gain.

Modeled from a vintage early '80s Pro Co Rat, the Raw Distortion plug-in for UAD-2 and Apollo interfaces is a faithful emulation of this legendary distortion box, delivering all of the grit, dynamics, and raunch of the original hardware.

Now You Can:

- Track through a faithful emulation of the incomparable Pro Co Rat with Apollo Twin, DUO, or QUAD
- Dial-in subtle grind or thick, saturated tones with the same pedal used by Jeff Beck, Johnny Greenwood, and Joe Walsh
- Add interesting overdriven textures to guitars, synths, drums, and vocals at mixdown with any UAD-2 hardware
- Get the same circuit interaction, gain range, and clip points for touch-sensitive tones, thanks to Unison[™] technology for Apollo interfaces

Trapping Raw for a Faithful Emulation The Raw Distortion plug-in for UAD-2 and Apollo interfaces captures the original hardware's unique, single op-amp circuit as well as its famous "backwards" passive tone filter. This powerful tone control is at the heart of the Rat's versatility, as it adds tube-like warmth to single-coils while also giving humbucker-equipped guitars an ultra-musical "slice" to stand out in a mix.

Raw Distortion is not affiliated with, sponsored nor endorsed by any companies currently using the Pro Co Rat name. The Raw Distortion name is used solely to identify the classic effect emulated by Universal Audio's product.

Subtle Bite or Grinding Gain	Just like the original Rat, the Raw Distortion for UAD-2 and Apollo excels at giving your tones a touch of "hair" – perfect for texture on chords – or all-out saturation and distortion. This versatility affords you bountiful sonic options with any guitar you plug in.
Unison Technology for Authentic Tone, Touch, and Feel	The interaction of your instrument and the first pedal in your signal chain is an essential ingredient to capturing a stompbox's unique character and tone. Thanks to Universal Audio's Unison technology, your guitar gets the same circuit interaction, gain range, and clip points of a vintage Pro Co Rat when you plug in to an Apollo Twin, DUO, or QUAD. This gives you the true tone, feel, and response of the original hardware.
Use the Raw on Any Source	The Raw Distortion's plug-in's singular voice can also be turned loose on bass, drums, vocals, or synths, giving you a unique tone sculpting tool. Give a sub- tle edge to a vocal or string patch, or bury a drum bus in a sea of molten dis- tortion for tracks that defy description.

Raw Distortion Screenshot

Figure 132. The Raw Distortion plug-in window

Using Raw

Standard DAW Inserts In much the same way as some premier recording and mix engineers use stomp boxes in a mix, Raw Distortion can be used for creative purposes on any source signal by placing it in any plug-in insert within a DAW. For typical guitar tones, follow the pedal with a guitar amp emulation (as one would with a hardware guitar pedal and amp).

> Because the plug-in accurately models the original hardware's high-impedance operating levels, precautions may need to be taken to avoid undesirable input clipping.

> **Note:** Since Hi-Z devices typically operate at much lower signal levels than line-level devices, signal levels being routed into the pedal may need to be reduced to avoid undesirable input distortion.

Unison™ Technology with Apollo Raw features Unison technology for integration with the high-impedance input hardware in Universal Audio's Apollo audio interfaces. With Unison, Apollo's Hi-Z inputs inherit all of the unique circuit interaction, gain range, and clip points of the original guitar pedal.

Hi-Z Signal Routing

For the most authentic stompbox tones, plug any high-impedance instrument (guitar, bass, etc.) into Apollo's Hi-Z instrument input and place the pedal plug-in into the unique Unison INPUT insert on the same channel within Apollo's Console application. If desired, follow the Unison pedal plug-in with another pedal or guitar amp emulation Console's standard insert slots.

This Hi-Z workflow enables near-zero latency monitoring or recording with the same input characteristics and dynamic response as the original pedal.

Note: This plug-in can be Unison-enabled with Apollo's Mic or Line inputs. However, because the original hardware has a high-impedance instrument input only, Apollo's Hi-Z input and Unison insert will provide the most accurate sound and experience of the hardware pedal that is modeled.

Important: Unison is active only when the pedal plug-in is placed in the unique INPUT insert available on Hi-Z inputs within Apollo's Console application. For complete Unison details, see the Apollo Software Manual.

Tactile Control

Apollo's front panel preamp knob can independently adjust the Distortion, Volume, and Output controls available within the Unison pedal plug-in via Gain Stage Mode. The control being adjusted can be remotely switched via Apollo, so the control levels and their associated colorations can be tuned from the hardware knob for precise physical tactile control, all without using the Unison plug-in's software interface.

Raw Controls

CHAPTER 44 RealVerb Pro

Overview

	RealVerb Pro uses complex spatial and spectral reverberation technology to accurately model an acoustic space. What that gets you is a great sounding reverb with the ability to customize a virtual room and pan within the stereo spectrum.
Room Shape and Material	RealVerb Pro provides two graphic menus each with preset Room Shapes and Materials. You blend the shapes and material composition and adjust the room size according to the demands of your mix. Controls are provided to ad- just the thickness of the materials – even inverse thickness for creative effects. Through some very clever engineering, the blending of room shapes, size and materials may be performed in real-time without distortion, pops, clicks or zip- per noise. Once you've created your custom room presets, you can even morph between two presets in real-time, with no distortion.
Resonance, Timing and Diffusion	RealVerb Pro also includes intuitive graphic control over equalization, timing and diffusion patterns. To maximize the impact of your recording, we put in- dependent control over the direct path, early reflections and late-field rever- beration in your hands.
Stereo Soundfield Panning	Capitalizing on the psychoacoustic technology that went into the design of RealVerb 5.1, we have incorporated some of those principals into RealVerb Pro. Our proprietary Stereo Soundfield Panning allows you to spread and control the signal between stereo speakers creating an impression of center and width. The ability to envelop your listener in a stereo recording is an en- tirely new approach to reverb design.
	Don't rely on your old standby. Let RealVerb Pro bring new quality and space to your recordings!

RealVerb Pro Background

Figure 133. RealVerb Pro signal flow

Figure 133 illustrates the signal flow for RealVerb Pro. The input signal is equalized and applied to the early reflection generator and the late-field reverberation unit. The resulting direct path, early reflection, and late-field reverberation are then independently positioned in the soundfield.

Figure 134. The RealVerb Pro plug-in window

The RealVerb Pro user interface is similarly organized (see Figure 134). Reflected energy equalization is controlled with the Resonance panel. The pattern of early reflections (their relative timing and amplitudes) is determined by the room shapes and sizes in the Shape panel; early reflection predelay and overall energy is specified at the top of the Timing panel. The Material panel is used to select relative late-field decay rates as a function of frequency. The overall late field decay rate is chosen along with the room diffusion, late-field predelay, and late-field level at the bottom of the Timing panel. Finally, the Positioning panel contains controls for the placement of the source, early reflections, and late-field reverberation.

Spectral Characteristics

The Shape and Material panels specify the room shape, room size, room material and thickness. These room properties affect the spectral characteristics of the room's reflections.

Shape and Size The pattern of early reflections in a reverb is determined by the room shape and size. RealVerb Pro lets you specify two room shapes and sizes that can be blended to create a hybrid of early reflection patterns. There are 15 room shapes available, including several plates, springs, and classic rooms; room sizes can be adjusted from 1–99 meters. The two rooms can be blended from 0–100%. All parameters can be adjusted dynamically in real time without causing distortion or other artifacts in the audio.

Figure 135. RealVerb Pro Shape panel

To configure the room shape and size:

- **1.** Select a room shape from the first (left) pop-up menu. The selected shape appears in the left side of the Shape circle. Adjust the room size with the top horizontal slider.
- 2. Select a room shape from the second (right) pop-up menu. The selected shape appears in the right side of the Shape circle. Adjust the room size with the bottom horizontal slider.
- 3. Blend the early reflection patterns of the two rooms by dragging the Blending bar. The relative percentages of the two rooms appear above their popup menus. Drag to the right to emphasize the first room shape; drag to the left to emphasize the second room shape. To use only one room shape, drag the Blending bar so the shape is set to 100%.

The resulting early reflection pattern is displayed at the top of the Timing panel (see Figure 138 on page 453), where each reflection is represented by a yellow vertical line with a height indicating its arrival energy, and a location indicating its arrival time.

Material and The material composition of an acoustical space affects how different frequency components decay over time. Materials are characterized by their absorption rates as a function of frequency—the more the material absorbs a certain frequency, the faster that frequency decays. RealVerb Pro lets you specify two room materials with independent thicknesses, which can be blended to create a hybrid of absorption and reflection properties. For example, to simulate a large glass house, a blend of glass and air could be used.

> There are 24 real-world materials provided, including such diverse materials as brick, marble, hardwood, water surface, air, and audience. Also included are 12 artificial materials with predefined decay rates. The thickness of the materials can be adjusted to exaggerate or invert their absorption and reflection properties. For a description of the different room materials, see "About the Materials" on page 449.

Figure 136. RealVerb Pro Material panel

Note: While materials are used to control decay rates as a function of frequency, the overall decay rate of the late-field reverberation is controlled from the Timing panel (see Figure 138 on page 453).

To configure the room material and thickness:

- **1.** Select a room material from the first (left) pop-up menu. The selected material appears in the left side of the Material circle.
- 2. Adjust the thickness for the first material with the top horizontal slider:
- A default thickness of +100% yields normal, real-world decays for the material.
- Thicknesses beyond the default (up to +200%) exaggerate how the frequencies are absorbed and reflected.
- Negative thicknesses invert the response of the material. If the material normally absorbs high frequencies (causing them to decay quickly) and reflects low frequencies (causing them to decay slowly), a negative thickness will instead absorb low frequencies (causing them to decay quickly) and reflect high frequencies (causing them to decay slowly).
- A thickness of 0% yields decay rates that are not affected by the material.
- **3.** Select a material from the second (right) pop-up menu. The selected material appears in the right side of the Material circle. Adjust the material thickness with the bottom horizontal slider.

4. Blend the absorption properties of the two materials by dragging the Blending bar. The relative amount of each material, expressed as a percentage, appears above their respective pop-up menu. Drag the Blending bar to the right to emphasize the first material, and drag it to the left to emphasize the second material. To use only one room material, drag the Blending bar so the material is set to 100%.

About the Materials Some materials absorb high frequencies and reflect low frequencies, while other materials absorb low frequencies and reflect high frequencies. This characteristic is determined by the material surface and density.

Fiberglass, for example, absorbs high frequencies. When high frequencies strike fiberglass they bounce around inside the fibers and lose much of their energy.

At a thickness of 100%, fiberglass rolls off the high frequencies, a little bit each millisecond. After a while the high frequencies dissipate and the low frequencies linger. If we were to take fiberglass and increase its thickness to +200%, the high frequencies would roll off even faster. At +200%, this high frequency decay happens at twice its normal rate, producing a very heavy reverberant tail. At -200%, a very "sizzly" late field is created.

Some materials, such as plywood, naturally absorb low frequencies while reflecting high frequencies. Since plywood is usually very flat with little surface texture to capture high frequencies, high frequencies tend to be reflected. At +100%, the reverberation produced is very sizzly and increasingly bright. At -100%, it is very heavy.

Keeping this in mind, if you look at the graphics in the material control panel, you can get a sense of how chosen materials, material blend, and thickness will affect the decay rate as a function of frequency. Hard materials that have lots of small cavities (Brick, Gravel, Plaster on Brick) and soft materials (Carpet, Grass, Soil) tend to absorb high frequencies. Flat, somewhat flexible materials (Heavy Plate Glass, Hardwood, Seats) tend to reflect high frequencies. Marble is the one material that tends to uniformly reflect all frequencies.

You probably noticed the artificial materials the top of the Materials menu. These are materials designed to have predictable behavior and can be very handy for achieving a desired reverberation preset when you know what decay rates you desire. All these materials preferentially absorb high frequencies; they give the selected decay time at low frequencies, and a much shorter decay time at high frequencies. The frequency in each graphic is the transition frequency, the frequency at which the decay rate is halfway between the low-frequency and high-frequency values. At 100% thickness, the ratio of lowfrequency to high-frequency decay times is 10:1. This means that the high frequencies will decay 10 times faster than the low frequencies. At 200% thickness, this is multiplied by two (high frequencies decay at 20x the rate of the low frequencies). At negative 100%, the sense of low frequency and high frequency is swapped —low frequencies decay 10 times faster than the high frequencies.

Many hardware and software reverbs tend to compensate for the high frequency absorption that air provides. RealVerb Pro instead provides "Air" as a material. If you do not choose to use Air as one of the materials, you can effectively compensate for the high frequency absorption properties of air with the Resonance filters. Set the right-hand Transition Frequency slider to 4.794 kHz, and bring the level down about -10 dB to -15 dB for large to huge rooms, and down about -4 dB to -9 dB for small to medium rooms.

To help you out, the following lists classify the materials under two headings: those that tend to reflect high frequencies, and those that tend to absorb them. They are listed in order of their transition frequencies, from lowest to highest.

Audience	Fiberglass
Cellulose	Grass
Drapery	Plaster on Brick
Plaster on Concrete Block	Water Surface
Soil	Sand
Gravel	Brick
Paint on Concrete Block	Air
Carpet	

Table 31. Materials with high-frequency absorption

Table 32. Materials with high-frequency reflection

Heavy Plate Glass	Seats
Plywood	Marble
Hardwood	Concrete Block
Glass Window	Linoleum
Cork	

Resonance (Equalization)

The Resonance panel has a three-band parametric equalizer that can control the overall frequency response of the reverb, affecting its perceived brilliance and warmth. By adjusting its Amplitude and Band-edge controls, the equalizer can be configured as shelf or parametric EQs, as well as hybrids between the two.

Figure 137. RealVerb Pro Resonance panel

To configure the reverb's Resonance as a parametric EQ:

- Drag the Band Edge controls horizontally for the second and third bands to the desired frequencies. The first band is preset to 16 Hz. The frequencies for all three bands are indicated in the text fields at the bottom of the Resonance panel.
- 2. Adjust the amplitude of the bands (from -60 dB to 0 dB) by dragging their Amplitude controls either up or down. The amplitude values for all three bands are indicated in the text fields at the bottom of the Resonance panel. The shape of the EQ curve is displayed in the Resonance graph.

To configure the reverb's Resonance as a high-shelf EQ:

- **1**. Drag the Amplitude control for the second EQ band all the way down.
- 2. Drag the Amplitude controls for the first and third bands all the way up, to equal values.

- 3. Adjust the Band-edge controls for the second and third bands so they are adjacent to each other. To raise the frequency for the high-shelf, drag to the right with the Band-edge control for the second band. To lower the frequency for the high-shelf, drag to the left with the Band-edge control for the third band.
- 4. To attenuate the frequencies above the shelf frequency, drag the Amplitude controls for the first and second bands up or down. For a true shelf EQ, make sure these amplitudes are set to equal values.

To configure the reverb's Resonance as a low-shelf EQ:

- **1**. Drag the Amplitude control for the second EQ band all the way up.
- **2.** Drag the Amplitude controls for the first and third bands all the way down, to equal values.
- 3. Adjust the Band-edge controls for the second and third bands so they are adjacent to each other. To raise the frequency for the low-shelf, drag to the right with the Band-edge control for the second band. To lower the frequency for the low-shelf, drag to the left with the Band-edge control for the third band.
- **4.** To attenuate the frequencies below the shelf frequency, drag the Amplitude controls for the first and second bands up or down. For a true shelf EQ, make sure these amplitudes are set to equal values.

Timing

The Timing panel offers control over the timing and relative energies of the early reflections and late-field reverberations. These elements affect the reverb's perceived clarity and intimacy. The early reflections are displayed at the top of the Timing panel, with controls for Amplitude and Pre-delay. The late-field reverberations are displayed at the bottom, with controls for Amplitude, Pre-delay, and Decay Time. To illustrate the relation between both reverb components, the shape of the other is represented as an outline in both sections of the Timing panel (see Figure 138).

To adjust the timing of the early reflections:

- Drag the Amplitude control for the early reflections up or down (from -80 dB to 0 dB) to affect the energy of the reflections. The Amplitude value is indicated in the text field at the bottom of the Timing panel.
- 2. Drag the Predelay control for the early reflections left or right (from 1–300 milliseconds) to affect the delay between the dry signal and the onset of early reflections. The Pre-delay time is indicated in the text field at the bottom of the Timing panel.

Note: The length in time of the early reflections cannot be adjusted from the Timing panel, and instead is determined by the reverb's shape and size (see Figure 135).

To adjust the timing of the late-field reverberations:

- **1.** Drag the Amplitude control for the late-field reverberations up or down (from –80 dB to 0 dB) to affect the energy of the reverberations. The Amplitude value is indicated in the text field at the bottom of the Timing panel.
- 2. Drag the Predelay control for the late-field reverberations left or right (from 1–300 milliseconds) to affect the delay between the dry signal and the onset of late-field reverberations. The Predelay time is indicated in the text field at the bottom of the Timing panel.

- **3.** Drag the Decay Time control for the late-field reverberations left or right (from 0.10–96.00 seconds) to affect the length of the reverb tail. The Decay Time is indicated in the text field at the bottom of the Timing panel.
- 4. To affect how quickly the late-field reverberations become more dense, adjust the Diffusion control at the right of Late Reflection display in the Timing panel. The higher the Diffusion value (near the top of the display), the more rapidly a dense reverb tail evolves.

Positioning

One of the unique features of RealVerb Pro is the ability to separately position the direct path, early reflections, and late-field reverberation. The Position panel (see Figure 139) provides panning controls for each of these reverb components. In addition, a proprietary Distance control adjusts perceived source distance. These controls allow realistic synthesis of acoustic spaces for instance listening at the entrance of an alley way, where all response components arrive from the same direction, or listening in the same alley next to the source, where the early reflections and reverberation surround the listener.

Note: The Direct, Early, and Late controls are unavailable in mono-in/monoout configurations.

Figure 139. RealVerb Pro Positioning panel

To pan the direct (dry) signal:

1. Drag the Direct slider left or right. A value of <100 pans the signal hard left; a value of 100> pans the signal hard right. A value of <0> places the signal in the center of the stereo field.

Set the positioning for the early reflection or late-field reverberation with any of the following methods:

- Drag the left and right slider handles to adjust the stereo width. The length of the blue slider is adjusted. For a full stereo signal, drag the left handle all the way to left, and right handle all the way to the right.
- 2. Drag the blue center of the slider left or right to set the positioning of the signal. If you drag all the way to the left or right, the stereo width is adjusted. For a mono signal panned hard left or right, drag the slider all the way to the left or right.
- **Distance** RealVerb Pro allows you to control the distance of the perceived source with the Distance control in the Positioning panel (see Figure 139). In reverberant environments, sounds originating close to the listener have a different mix of direct and reflected energy than those originating further from the listener.

To adjust the distance of the source:

- **1.** Drag the Distance slider to the desired percentage value. Larger percentages yield a source that is further away from the listener. A value of 0% places the source as close as possible to the listener.
- Wet/Dry Mix The wet and dry mix of the reverb is controlled from the Mix slider in the Positioning panel (see Figure 139). The two buttons above this slider labeled "D" and "W" represent Dry and Wet; clicking either will create a 100% dry or 100% wet mix.

Levels

The Levels panel adjusts the Input Gain and Output Gain for RealVerb Pro. These levels are adjusted by dragging the sliders to the desired values. You can mute the input signal by clicking the Mute button.

Levels								
Mute	CLIP	- 🗔	CLIP					
	5		5					
	10		10					
	15 -		15					
	20		20					
	25		25					
	30	-	30					
	35		35					
0.0 dB								
Input Gain Output Gain								

Figure 140. RealVerb Pro Levels panel

Morphing

All RealVerb Pro controls vary continuously using proprietary technology to smoothly transition between selected values. This capability enables RealVerb Pro to morph among presets by transitioning between their parameter sets. This approach is in contrast to the traditional method of morphing by crossfading between the output of two static reverberators. The method employed by RealVerb Pro produces more faithful, physically meaningful intermediate states.

Figure 141. RealVerb Pro Morphing panel

Figure 141 depicts the Morphing Panel. Click the Morphing Mode button to enable Morphing mode. When RealVerb Pro is in morphing mode, the other RealVerb Pro spectral controls are grayed out and cannot be edited. In morphing mode, two presets are selected using the pull-down menus. Once the desired presets are selected in the pull-down menus, the morphing slider is used to morph from one preset to the other. When in Morphing mode (Figure 142 on page 457), non user-adjustable con trols will change their appearance and will no longer be accessible. When in serted on a Send effect, the 'W' button automatically turns on (to keep the mix at 100% wet).

On an insert effect, the Mix will change back and forth between the two mix values of each preset.

Figure 142. RealVerb Pro in Morphing mode

RealVerb Pro Preset Management

Factory Presets In the preset menu there are thirty factory presets that can be changed by the user. Any modification to a preset will be saved even if you change presets. If you want to return all the presets to their default settings, select "Reset all to Defaults" at the bottom of the presets menu.

Edits to any and all presets in the list are maintained separately within each instance of a plug-in within a session.

Using Host Most host applications include their own method of managing plug-in presets. Application

Management For example, the currently selected preset is saved in Cubase/Nuendo when "Save Effect" is used. Morphing parameters and the solo/mute buttons (wet, dry, input) are not saved.

All presets and programs are saved in Cubase/Nuendo when "Save Bank" is used. They are also saved in the session file for each instance of the plug-in.

Editing the name in Cubase/Nuendo modifies the current preset's name. The new name will appear in all preset select lists, and will be saved with the session, bank or effect.

RealVerb Pro Preset List

Acoustic Guitar	Hairy Snare
Apartment Living	High Ceiling Room
Big Ambience	Jazz Club
Big Bright Hall	Large Bathroom
Big Cement Room	Large Dark Hall
Big Empty Stadium	Long Tube
Big Snare	Medium Drum Room
Big Warm Hall	Nice Vocal 1
Cathedral	Nice Vocal 2
Church	Slap Back
Dark Ambience	Small Bright Room
Drums in a Vat	Small Dark Room
Eternity	Sparkling Hall
Far Away Source	Tight Spaces
Ghost Voice	Wooden Hall

CHAPTER 45

Boss CE-1 Chorus Ensemble

Overview

The Boss CE-1 Chorus Ensemble is another classic effect faithfully reproduced by our ace modeling engineers. The CE-1 is considered by many to the definitive chorus effect, renowned for its rich and unique timbres.

Even for the mix engineer, stomp boxes can provide "secret weapon effects" not found any other way. In 1976, BOSS originated the chorus effect pedal, and nobody has come close to matching the CE-1's captivating chorus sound since then. Its unmistakable warm analog stereo chorus and vibrato have been heard on countless tracks; particularly on guitars, bass and electric keys. Universal Audio has been commissioned by Roland to accurately model the CE-1, and the results are nothing short of spectacular.

Boss CE-1 Screenshot

Figure 143. The Boss CE-1 plug-in window

Boss CE-1 Controls

The Boss CE-1 has two operating modes, chorus and vibrato. Only one mode can be active at a time. The operating mode is set using the Vibrato/Chorus switch.

The red Clip LED illuminates when signal peaks in the plug-in occur.

Clip LED

Normal/Effect Switch

This is an effect bypass switch. Click to enable/disable the chorus or vibrato effect. The effect that will be heard is determined by the Vibrato/Chorus switch.

The active state is black text. The inactive state has gray text. The default state is effect.

This is not a plug-in bypass switch. The hardware CE-1 has a slight affect on the sound even when the effect is "bypassed" in normal mode. We have modeled the plug-in faithfully and like the hardware unit, when the effect is bypassed with this switch, audio is still processed to sound like the CE-1 in "normal" mode. To disable audio processing, use the CE-1 Power Switch.

Rate LED

The yellow Rate LED blinks according to the current low-frequency oscillator (LFO) rate. When CE-1 is in Vibrato mode, the LFO rate is determined by the vibrato rate knob. When in Chorus mode, this LED is affected by the Intensity knob.

Note: In Chorus mode, the fastest LFO rate is slower than the slowest LFO rate in Vibrato mode.

Vibrato/Chorus Switch

This switch determines the operating mode of the plug-in. Click to switch between chorus and vibrato modes.

The active mode is black text. The inactive mode has gray text. The default mode is chorus.

Stereo ModeThe Stereo Mode switch determines the operating mode of CE-1 when the
plug-in is used in a stereo or mono-to-stereo configuration, such as a stereo au-
dio track insert or stereo effects bus.

The hardware CE-1 has only a monophonic input. Its output can be mono (wet and dry signal mixed at one output jack) or stereo (dry signal in one output jack, wet signal in other output jack). We've adapted the model for the modern era, enabling a true stereo input.

Note: This switch has no affect in a mono-in/mono-out configuration.

The Stereo Mode switch affects the output as follows:

Dual Mode

In Dual mode the CE-1 behaves as a dual-mono device, functioning as two independent CE-1's, each running in mono mode on one side of the stereo signal.

The left output contains a mix of the dry left input signal and the processed left channel signal, while the right output contains a mix of the dry right input signal and the processed right channel signal. Additionally, the LFO's of the dual CE-1 channels are 90 degrees out of phase (quadrature) for maximum effect.

Classic Mode

In Classic mode, the CE-1 behavior is similar to that of a mono-in/stereo-out configuration. The left and right channel inputs are mixed to mono, and the dry signal (mixed left and right channels) appear at the left output, and the wet effect signal appears at the right output.

Output Level Knob

This knob determines the signal level at the output of the plug-in. The range is 0 - 100%.

Note: This is not a wet/dry mix control.

Chorus Intensity Knob

When CE-1 is in chorus mode, the amount of chorusing effect is determined by this knob.

Note: When in vibrato mode, chorus intensity has no affect.

Vibrato Controls

These two knobs control rate and depth of the vibrato effect when CE-1 is in vibrato mode.

Depth Knob

The depth knob controls the intensity of the vibrato effect.

Rate Knob

The rate knob controls the rate of the vibrato LFO. The rate is indicated by the the Rate LED indicator.

Note: When in chorus mode, the vibrato controls have no affect.

Power Switch

This switch determines whether the plug-in is active. This is useful for comparing the processed settings to the original signal, or to bypass the plug-in to reduce the UAD DSP load (load is not reduced if DSP LoadLock is enabled).

Click the rocker switch to change the Power state.

CHAPTER 46

Roland Dimension D

Overview

The Roland SDD-320 Dimension D is another classic effect faithfully reproduced by our ace modeling engineers. The Dimension D is a one of a kind studio gem that adheres to the principle of doing one thing, and doing it extremely well. Its one and only function: some of the best sounding stereo chorus ever made. However, the Dimension D is more than a chorus, it is really a unique sound enhancer for adding spatial effects to mono or stereo sources. The Dimension D does not create a dramatically new sound, but enhances the characteristics of any voice or instrument, and gives a new "dimension" without the apparent movement of sound produced by other chorus devices. The strength of the Dimension D is in its subtlety.

This classic 1979 Roland device has been heard on countless records, from luminaries such as Peter Gabriel, Talking Heads and INXS. Entrusted by the Roland company to emulate this classic studio tool, Universal Audio went to great lengths to preserve this Bucket Brigade chorus with all its unique design elements and sonic characteristics. With only four pushbutton 'dimension' settings, the Dimension D is the ultimate in functional simplicity.

Roland Dimension D Screenshot

Figure 144. The Roland Dimension D plug-in window

Roland Dimension D Controls

The Roland Dimension D is very simple device to operate; it has only three controls: Power, Mono, and Mode. Each control is detailed below.

Dimension Mode

The Dimension Mode determines the effect intensity. Four different modes are available. Mode 1 is the most subtle effect, and Mode 4 is maximum intensity.

Multiple Buttons True to the original hardware, multiple Dimension Mode buttons can be engaged simultaneously for subtle sonic variations of the four main modes. To engage multiple Dimension Mode buttons, press the Shift key on the computer keyboard while clicking the Mode buttons.

Input Mode Switch

The original Roland Dimension D has an input switch on the back that puts the unit into mono-in/stereo-out mode. We have included this function and moved the switch "to the front" for your processing convenience.

When in Mono mode, the input to Dimension D is monophonic even when used in a stereo-input configuration (stereo inputs are summed to mono). This can be useful for sonic variation, such as when the plug-in is used in an auxiliary/effect send configuration.

The default position (in) is stereo mode. Click the pushbutton switch (out) to enable Mono mode.

Power Switch This switch determines whether the plug-in is active. This is useful SDD-320 for comparing the processed settings to the original signal, or to POWER bypass the plug-in to reduce the UAD DSP load (load is not re-= ON duced if UAD-2 DSP LoadLock is enabled). Click the pushbutton switch to change the Power state.

Power LED The Power LED is illuminated when the plug-in is active.

Output Level

This LED-style meter indicates the level of the signal at the output of the plug-in.

When the Dimension Mode is OFF but the Power switch is ON, audio is not processed but the Output Level meter is still active.

Roland RE-201 Space Echo

Overview

In 1973, Roland created the Space Echo system that utilized multiple play heads to create warm, highly adjustable echo effects, which added wonderful tape character and chaos to performances and recordings. The Space Echo can be heard on numerous recordings, from 70's space rock like Pink Floyd and David Bowie, to countless Reggae and Dub albums, to more recent bands like Portishead and Radiohead. Universal Audio has been entrusted by Roland to re-create the highly beloved RE-201 unit, considered the best of the Space Echo line. Our team spent over a year developing our RE-201 Space Echo, which truly captures the physical behavior of this complex device "warts and all", down to the distortion, wow and flutter, pitch shifting, and warmth that tape based delays are famous for; but our plug-in goes even further, capturing the complex self-oscillation that makes the Space Echo more than an effect, but a unique instrument unto itself.

UA's RE-201 Space Echo faithfully retains all the controls and features of the original, such as the Mode Selector for various head combinations, Repeat Rate for fine timing control, and Intensity which sets repeat count and allows the unit to achieve self-oscillation. The all-important Echo/Normal "Dub" switch is retained for muting, as well as the simple tone controls. Last but certainly not least, the atmospheric shimmer of the Space Echo's spring reverb is faithfully captured, putting this fantastic plug-in on par with the original unit as a tool of infinite creativity.

Roland RE-201 Screenshot

Figure 145. The Roland RE-201 plug-in window

Roland RE-201 Interface

The RE-201 interface is true to the original hardware, with a few customizations to bring it into the digital era.

The original mic and instrument volume controls have been replaced with echo/reverb pan controls and an input control. We've also added a "Tape Age" switch to emulate new and older tape, a Wet Solo control for use as a bus/send effect, and an output volume control for utility. The clever "Splice" switch allows the user to trigger the tape splice at will.

Tempo synchronization controls round out the modernization of this classic analog processor. The fabulous sound of the original is untouched!

Roland RE-201 Controls

Each feature of the Roland RE-201 interface is detailed below.

Peak Level

The Peak lamp indicates when transient signal peaks and clipping are detected just after the input volume control. It begins illuminating at approximately –2 dB to –1.5 dB, then gets brighter as the level increases.

VU Meter

The VU meter indicates the average signal that is about to be written to the "tape." Used in conjunction with the Peak lamp, an indication of signal level can be deduced. The VU is essentially an input meter, therefore it doesn't react when the Echo/Normal switch is switched from Echo to Normal.

Note: The Peak lamp and VU meter measure signal just after the input volume control. However, like the original hardware, echo intensity (feedback) is applied just before the level detection circuit. For this reason, the Intensity control will affect the level readings.

Echo Pan

Echo Pan determines the placement of the echo signal in the stereo panorama when the plug-in is used in mono-in/stereo-out and stereo-in/stereo-out configurations. When the RE-201 is used in a mono-in/mono-out configuration, this control is disabled.

Reverb Pan

Reverb Pan determines the placement of the reverb signal in the stereo panorama when the plug-in is used in mono-in/stereo-out and stereo-in/stereo-out configurations. When the RE-201 is used in a mono-in/mono-out configuration, this control is disabled.

Input Volume

This control determines the signal level that is input to the plug-in. Unity gain is at the 12 o'clock position.

Like the original hardware, clipping distortion at the input to the plug-in affects the tone of the echo and reverb. Clipping is often used as part of the desired effect. At unity gain clipping can be

easily induced. However if a cleaner sound is desired, reduce the input volume below unity and increase the plug-in output volume to compensate.

Mode Selector

The RE-201 is a combination of a tape echo and a spring reverb effect. Echo, reverb, or both can be selected with the Mode Selector to determine which effect(s) are active.

The original Space Echo has three tape playback heads. By changing the combination and positions of the heads, a total of 12 different echo variations can be obtained (4 echo only, 7 echo/reverb, and 1 reverb

only). These modes are faithfully reproduced with the UAD Roland RE-201.

Note: The RE-201 uses less UAD DSP in reverb-only or echo-only modes versus when both modes are used simultaneously.

The affect of each knob position is detailed in Table 34 on page 468.

Mode Knob			RI (ec	EPEA1 ho onl	г у)	REVERB + ECHO				REVERB ONLY			
Posi	ition	1	2	3	4	5	6	7	8	9	10	11	Reverb
Active	1	•				•			•		•	•	
Tape	2		•		•		•		•	•		•	
Heads	3			•	•			•		•	•	•	
Active Reverb		•	•	•	•	•	•	•	•				

Table 34. RE-201 Mode Selector Positions

Bass

This knob controls the low frequency response in the tape echo portion of the signal. It does not affect the dry signal or the reverb signal. This is a cut/boost control; it has no effect when in the 12 o'clock (straight up) position.

Treble

This knob controls the high frequency response in the tape echo portion of the signal. It does not affect the dry signal or the reverb signal. This is a cut/boost control; it has no effect when in the 12 o'clock (straight up) position.

Reverb Volume

This control determines the volume of the spring reverb effect. Rotate the control clockwise for more reverb. Reducing the control to its minimum value will disable the reverb.

On the original hardware the reverb output is quite low, and

with some sources, unusable due to a high noise floor. Our model of the spring reverb has no noise, and has an increased available output level to improve usability.

Note: Reverb Volume has no affect when the Mode Selector is in positions 1 through 4.

Output Volume

This control determines the output volume of the plug-in. It affects the dry and effect signals.

The range of this control is ±20 dB from unity gain. Therefore, some signal may still be heard when this control is set to its minimum value.
Repeat Rate

This knob controls the time interval of the echo effect. Rotating the control clockwise will decrease the delay time, and counterclockwise rotation will increase the delay time.

The available delay times are as follows:

- Head 1: 69ms 177ms
- Head 2: 131ms 337ms
- Head 3: 189ms 489ms

The head times available with this control are dependent upon the "Mode Selector" on page 467. As with the original hardware, this control varies the tape playback speed in realtime by manipulating the tape capstan motor and therefore has a musically useful "ramp-up" and "ramp-down" effect.

When Tempo Sync is enabled, this control is quantized to allow only rhythmic notes available at the leading head.

Intensity

This knob controls the repeat level (feedback) of the echo signal. Rotating the control clockwise increases the number of echoes. Higher values will cause self-oscillation; the exact position is program and Mode dependent.

The self-oscillation of the RE-201 is one of the magic features that really makes it more than a mixing tool; it's also an instrument to be played. The effect may be used subtly, sending the unit into gentle oscillation on held notes, or can be put into "over the top" oscillation with extreme intensity settings. Different Modes will reveal different qualities of oscillation. Single head Modes tend to have simpler oscillation qualities, while multiple head modes will have a more complex sound when oscillating.

The RE-201's oscillation qualities are heavily program and control dependent. Different sources of audio, gain, tone, repeat rate, and tape settings will all effect "oscillation performance." The RE-201 can also achieve oscillation with no signal, making the RE-201 a truly unique instrument.

Echo Volume

This control determines the volume of the echo effect. Rotate the control clockwise for louder echo. Reducing the control to its minimum value will disable the echo. **Note:** Echo Volume has no affect when the Mode Selector is in the "Reverb Only" position.

Power Switch	This switch determines whether the plug-in is active. This is use- ful for comparing the processed settings to the original signal, or to bypass the plug-in to reduce the UAD DSP load. Toggle the switch to change the Power state.
	Toggling the power switch will also clear the tape echo. This can be useful if the RE-201 is self-oscillating and restarting the feedback loop is desired.
Echo/Normal	This switch disables the signal sent into the echo portion of the processor when set to NORMAL. The switch will have no effect if "Mode Selector" on page 467 is set to "Reverb Only." This control is some- times affectionately referred to as the "dub" switch.
Sync	This switch puts the plug-in into tempo sync mode. See Chapter 8 "Tempo Sync" in the UAD System Manual for more information.
Delay Time Display	These LCD-style readouts display the current de- lay time(s) of the RE-201. The three displays correspond to the three virtual "heads" in the plug-in, and always maintain their proportional relationship to each other.
	The delay time values are displayed in milliseconds unless tempo sync is ac- tive, in which case beat values are displayed. When a particular head is in- active (see "Mode Selector" on page 467), a dash is displayed.
	When in tempo sync mode, note values that are out of range will flash. Im- precise note values due to head relationships are displayed with superscript + or – symbol before the note.
Tape Age	In the original hardware, the tape loop is contained in a user-re- placeable cartridge. As the tape wears out, it is subject to fidelity loss plus increased wow and flutter. The Tape Age switch allows the plug-in to mimic the behavior of new, used, and old tape car- tridges.

Newer tape may be ideal for a pristine vocal track, while older tape could be described as having more "character" and might be more appropriate for sources where greater chaos may be musical.

Normally, the splice on the tape loop comes around at regular intervals. This interval varies, and is determined by the selected Repeat Rate. Depending on what Tape Quality is selected, the splice can be subtle or obvious, and can work as a catalyst for chaos es-

pecially when the RE-201 is in a state of self-oscillation.

This switch resets the location of the tape "splice" when the switch is actuated. It is a momentary switch that pops back into the off position immediately after it is activated, allowing the user to trigger the splice point at will.

Note that the splice effect isn't immediate. It drops the splice at the write head, and it needs time to go over the read heads (at which point there will be a dropout), and then the tape capstan (where it will create some wow and flutter).

Wet Solo

When this switch is OFF, the dry/unprocessed signal is mixed with the wet/processed signal. When set to ON, only the processed signal is heard.

Wet Solo is useful when the plug-in is placed on an effect group/bus that is configured for use with channel sends. When the plug-in is used on a channel insert, this control should generally be OFF.

Note: Wet Solo is a global (per RE-201 plug-in instance) control.

Caution :-D If the RE-201 generates noise after installation, changing the location or position is indicated to correct the situation. Avoid prolonged use in dusty, hot or high humidity places.

The Roland RE-201 original hardware unit

CHAPTER 48

SPL Transient Designer

Overview

Universal Audio has partnered with German company Sound Performance Lab (SPL) to bring you the Transient Designer, with its unique and compelling Differential Envelope Technology for shaping the dynamic response of a sound. Only two simple audio controls are required to allow you to effortlessly reshape the attack and sustain characteristics. SPL was the first company to design an analog solution for level-independent shaping of envelopes, allowing transients to be accelerated or slowed down and sustain prolonged or shortened.

You can shorten or lengthen the attack and sustain of percussive signals such as kick drum, snare or toms, easily take the bleed from open mics, or expand the room sound of overheads. The Transient Designer's magic can be applied to virtually any other signal as well: Amplify or reduce the picking sound of an acoustic guitar, hold the sound of strings longer, or reduce the reverb time of a choir.

SPL Transient Designer Screenshot

Figure 146. The SPL Transient Designer plug-in window

SPL Transient Designer Controls

Containing only two primary controls, the UAD SPL Transient Designer is extremely simple to operate. The technology behind the processor isn't as important as how it sounds. However, for those who desire a deeper understanding of the process, a deeper explanation of the underlying technology is presented at the end of this chapter (see "Technology" on page 479).

Attack

Sustain

Attack enables amplification or attenuation of the attack of a signal by up to ± 15 dB.

The Attack control circuitry uses two envelope generators. One follows the shape of the original curve and adapts perfectly to the dynamic gradient. The second envelope generator produces an envelope with a slower attack. From the difference of both en-

velopes the VCA control voltage is derived. Positive Attack values emphasize attack events; negative values smooth out the attack envelopes of sound events.

For more information, see "The ATTACK Control Circuitry" on page 479)

Sustain enables amplification or attenuation of the sustain of a signal by up to ± 24 dB.

The Sustain control circuitry also uses two envelope generators. One follows the shape of the original curve and adapts perfectly to the dynamic gradient. The second envelope generator produces an

envelope with a longer sustain. From the difference of both envelopes the VCA control voltage is derived. The gradient of the control voltage matches the time flow of the original signal. Positive Sustain values lengthen the sustain; negative values shorten the sustain.

For more information, see "The SUSTAIN Control Circuitry" on page 481.

Gain

Gain controls the signal level that is output from the plug-in. The available range is from -20 dB to +6 dB. The default value is 0 dB. Signal

This 4-stage "LED" indicates the presence of audio signals at the input of the plug-in. When the input signal is below –25 dB, the indicator is off. At -25 dB to -19 dB, the indicator glows slightly. At -18 dB to -10 dB, it lights with medium intensity. At -9 dB to 0 dB, it shines brightly.

Overload

The Overload "LED" illuminates when the signal level at the output of the plug-in reaches 0 dBFS. The indicator matches the behavior of the original hardware unit. However, in the software plug-in version, the output can be "overloaded" without causing distortion.

Link

Link indicates when stereo operation is active. It illuminates when used in a stereo-in/stereo-out or mono-in/stereo out configuration. It does not illuminate when used in a mono-in/mono-out configu-

ration.

Note: Link is an indicator only; it does not control any plug-in parameter.

On/Power

The On and Power switches determine whether the plug-in is active. Click the On or Power switches to change the state. On and Power illuminate when the plug-in is active.

When the plug-in is inactive, processing is disabled and UAD DSP usage is reduced (unless UAD-2 DSP LoadLock is enabled).

Note: The On and Power switches perform the exact same function.

Acknowledgement

In addition to creating an amazing piece of hardware, Sound Performance Lab also wrote an extensive user manual for the Transient Designer. Because Universal Audio has full license to make use of the Transient Designer technology, SPL has graciously authorized us to use their documentation as well.

The remainder of this chapter is excerpted from the SPL Transient Designer (RackPack) User Manual, and is used with kind permission from SPL. All copyrights are retained by SPL.

Applications

The SPL Transient Designer is ideally suited for use in professional recording, in project or home studios and sound reinforcement applications.

For the first time you can manipulate and control the attack and sustain characteristics of a signal regardless of level in the most intuitive and simple way. Usually equalizers are used to separate instruments in a mix – the tonal aspect of the signal is considered, but not the temporal aspect.

The Transient Designer opens this further dimension in signal processing. By manipulating the attack and sustain curves of a sound event, the mix can be made to sound more transparent. Instruments can be mixed at lower levels while still maintaining their positions in the mix—but occupying less space.

During a remix or in general after micing you can arrange new positions of instruments. Reduce ATTACK and increase SUSTAIN to move signals back into the mix that are too present. Additionally the FX parts of too dry signals are strengthened.

Applied to single instruments or loops the Transient Designer allows you to create entirely new sounds and/or effects.

The following examples are given as suggestions and examples. The described procedures with specific instruments can of course be transferred to others that are not mentioned here.

Drums & Percussions Processing drum and percussion sounds is probably the Transient Designer's most typical range of application; both from samples to live drum sets

• Emphasize the attack of a kick drum or a loop to increase the power and presence in the mix.

- Shorten the sustain period of a snare or a reverb tail in a very musical way to obtain more transparency in the mix.
- When recording a live drum set, shorten the toms or overheads without physically damping them. Usual efforts to damp and mike are reduced remarkably. Since muffling of any drum also changes the dynamic response, the Transient Designer opens up a whole new soundscape.
- Micing live drums is considerably faster and easier because you can correct the apparent "distance" of the microphone by simply varying the ATTACK and SUSTAIN values.
- The Transient Designer is a perfect alternative to noise gates in live drum micing. Adaptively reacting to the duration of the original signal, the sustain is shortened more musically than with fixed release times and a drumset is freed from any crosstalk quickly and effectively.
- Create unusual dynamic effects including new and interesting pan effects. For example, patch a mono loop through two channels of the Transient Designer and pan fully left and right in the mix. Process the left channel with increased ATTACK and reduced SUSTAIN while you adjust the right channel the opposite way and you get very special stereo loop sounds. You have to try this to appreciate what it sounds like, but expect to hear a lot of unusual stereo movement.
- Enjoy an amazingly simple integration of drum sounds into a mix. If the acoustic level of a snare is expanded to approximately +4 dB by increasing the attack value, the effective increase of peak levels in the overall mix is merely about 0.5 dB to 1 dB.
- Drums: Ambience If your drums happen to sound as if the room mics have been placed in a shoe closet, the Transient Designer can immediately turn that sound into the ambience of an empty warehouse. Just send the stereo room mics through the Transient Designer and crank the ATTACK control to emphasize the first wave.

Now slowly increase SUSTAIN values to bring up an "all-buttons-in-1176sound" room tone—but without pumping cymbals. For a solid and driving rhythm track just fine-tune the SUSTAIN control to make sure that the room mic envelope ends more or less exactly on the desired upbeat or downbeat.

Guitars	Use the Transient Designer on guitars to soften the sound by lowering the AT- TACK. Increase ATTACK for in-the-face sounds, which is very useful and works particularly well for picking guitars. Or blow life and juice into quietly played guitar parts.
	Distorted guitars usually are very compressed, thus not very dynamic. Simply increase the ATTACK to get a clearer sound with more precision and better intonation despite any distortion.
	Heavy distortion also leads to very long sustain. The sound tends to become mushy; simply reduce SUSTAIN to change that. If you, how- ever, want to cre- ate soaring guitar solos that would make even David Gilmour blush, just crank up the SUSTAIN control to the max and there you go.
	With miced acoustic guitars you can emphasize the room sound by turning up SUSTAIN. If you want the guitars to sound more intimate and with less ambience, simply reduce SUSTAIN.
Bass: Staccato vs. Legato	Speaking of bass: Imagine a too sluggishly played bass track you may not have to re-record it: Reduce the SUSTAIN until you can hear clear gaps be- tween the downbeats—the legato will turn into a nice staccato, driving the rhythm-section forward.
The Re- Invention Of Reverb	Always and everywhere the same reverb presets – boring, aren't they? Try sending the output of your reverb through the Transient Designer. Now crank the ATTACK control to the max and reduce SUSTAIN to a bare minimum. The intensity of the reverb is now much higher in the beginning while the reverb time is reduced.
	The opposite can be just as intriguing: manipulate a reverb pattern so that it takes on a pyramidal slope. Turn the ATTACK all the way to the left and SUS-TAIN all the way to the right. Now the beginning of the reverb is strongly reduced whereas the sustain blossoms and seems almost endless (obviously that will only happen if the decay of the reverb in the actual reverb device has been set to a sufficient value—a signal must always be present as long as the sustain time lasts.
	You can also create a reverb effect that moves from one channel to the other. Reverb presets with a long decay or a long pre-delay and especially those that have flamboyant reflections set to appear after the beginning of the dif- fuse reverberation tail are predestined for that. Insert the left and the right

	channels of the reverb return through two separate Transient Designer in- stances. Turn the ATTACK fully right on one instance and reduce SUSTAIN slightly (about -1.5 dB). On the other instance turn the ATTACK fully left and the SUSTAIN to the 3-o'clock position (about +12 dB).
	These settings preserve the original complexity of the reflections in the reverb but the maximum intensity of the effect will move from the left to the right in the mix while the reverb will maintain it's presence in both channels. You can make this effect even more dramatic by setting all controls to their most ex- treme positions, but you run the danger of ending up with a lopsided effect that appears out of balance.
Backings	A common problem especially with tracks that are recorded and mixed in dif- ferent studios: Backings lack of ambience, and finding a reverb that "matches" takes time so simply emphasize the original ambience by turning up the Transient Designer's SUSTAIN control.
	And the opposite problem, too much ambience, is similarly simply solved with the opposite processing —just reduce SUSTAIN.
Keyboards & Sampler	Sounds in keyboards and samples are usually highly compressed and main- tain only little of natural dynamics. Increase the ATTACK values to re-gain a more natural response characteristic. The sounds occupy less space in the mix and appear more identifiable even at lower volumes.
Post Production	When dealing with overdubs in movies you can easily add more punch and definition to effect sounds from any sample library.
	The same applies to outdoor recordings that suffer from poor microphone po- sitioning—simply optimize them afterwards.
Mastering	Like with any good thing, you also have to know where not to use it. For ex- ample, using a Transient Designer in mastering is not recommended, as it is rarely a good idea to treat a whole mix at once. Instead, treat individual ele- ments within the mix.

Technology	
	Of course you don't have to know how the Transient Designer works in order to use it. However, since it offers a completely novel signal processing, noth- ing shall be concealed from the more curious users.
Differential Envelope Technology (DET)	SPL's DET is capable of level-independent envelope processing and thus makes any threshold settings unnecessary. Two envelopes are generated and then compared. From the difference of both envelopes the VCA control volt- age is derived. The DET ensures that both low and loud signals (pianissimo to fortissimo) are treated the same way.
	Both ATTACK and SUSTAIN control circuitries operate simultaneously and don't affect each other.
The ATTACK Control Circuitry	The ATTACK control circuitry uses two envelope generators. The first one generates a voltage (Env 1) that follows the original waveform. The second envelope generator creates the envelope Env 2 with a slower attack envelope.
	Figure 147 on page 479 illustrates the original curve and the two created envelopes that control the ATTACK processing. Envelope generator Env 1 follows the original waveform. Env 2 is generated with reduced attack.

Figure 147. SPL Transient Designer Attack Envelopes

Figure 148 on page 480 shows the difference between Env 1 and Env 2 that defines the control voltage of the VCA. The shaded area marks the difference between Env 1 and Env 2 that controls the control voltage of the VCA. The amplitude of the attack is increased if positive ATTACK values are set. Negative ATTACK values reduce the level of the attack transient.

U/mV Difference Env 1-Env 2 (Equals VCA Control Voltage) t/ms

Diagram 2: Calculated Control Voltage (Attack)

Figure 148. SPL Transient Designer Attack Control Voltage

Figure 149 on page 480 displays the processed waveforms with maximum and minimal ATTACK to compare against the original waveform in diagram 1.

Figure 149. SPL Transient Designer Processed Attack

The SUSTAIN Control Circuitry

The SUSTAIN control circuitry also plays host to two envelope generators. The envelope tracker Env 3 again follows the original waveform. The envelope generator Env 4 maintains the level of the sustain on the peak-level over a longer period of time. The control voltage of the VCA is again derived from the difference between the two voltages. Sustain amplitude is increased for positive SUSTAIN settings and reduced for negative settings.

Figure 150 on page 481 illustrates the original waveform and the envelope creation to control the SUSTAIN processing. Envelope generator Env 1 follows the original waveform, Env 2 is generated with prolonged sustain.

Figure 150. SPL Transient Designer Sustain Envelopes

Figure 151 on page 481 shows the difference between Env 4 and Env 3 that defines the control voltage of the VCA.

Figure 151. SPL Transient Designer Sustain Control Voltage

Figure 152 on page 482 displays the processed waveforms with maximum and minimal sustain to compare against the original waveform in diagram 4.

Figure 152. SPL Transient Designer Processed Sustain

CHAPTER 49 SSL E Channel Strip

Large Format Mix Module

The SSL 4000 is famous as the console employed on more Platinum-selling records than any other. With its wide range of VCA compression characteristics and intuitive EQ — rich with colorful band interdependencies — it's easy to hear why. Today, working in close partnership with Solid State Logic®, UA proudly unveils the SSL E Series Channel Strip plug-in for UAD-2 — an exacting circuit emulation of this certified hit-making machine.

The SSL E Series Channel Strip plug-in allows UAD-2 users on Mac and PC to apply classic SSL 4000 EQ curves and dynamics control to their music. This unique plug-in is distinguished by its remarkably authentic sound, and its inclusion of both the Type E "black knob" and "brown knob" four-band EQ and filters, long considered favorites in SSL lineage. Other features include high and low cut filters, independent Expander/Gate, and bespoke Compressor/Limiter.

The E Series' middle EQ bands are fully parametric, while the high and low bands provide the user with switchable bell or shelving filters. The Comp/Limiter provides Threshold, fast or slow Attack time, a 0.1 to 4 second Release, and a continuously variable Ratio control. The Exp/Gate offers Threshold, fast or slow Attack time, a 0.1 to 4 second Release time, and a Range control to tailor the Gate or Expansion effect. In addition, the SSL E Series Channel Strip plug-in adds a second Gate setting, featuring a "no-chatter" circuit borrowed from later SSL designs.

For increased flexibility, a PRE-DYN button allows users to reorder the signal chain, placing the EQ before the dynamics section. With the DYN-SC button, users may engage a sidechain feature, providing frequency-dependent compression using the EQ filters, cut filters, or both. Lastly, a Link button adds the ability to link or unlink the sidechain when using the stereo version of the plug-in.

Taken together, these features make the SSLE Series plug-in for UAD-2 among the most flexible and best-sounding channel strip emulations available today, bar none.

SSL E Channel Strip Screenshot

Figure 153. The UAD SSL E and 4K Channel Strip plug-in windows

SSL E Channel Strip Controls

The SSL E Channel Strip controls are divided into four main sections: filters, dynamics, EQ, and global.

Note that knob settings, when compared to the graphical user interface silkscreen numbers, may not match the actual parameter values. This behavior is identical to the original hardware, which we modeled exactly. When the plug-in is viewed in parameter list mode (Controls View), the actual parameter values are displayed.

Note: SSL consoles adopt a different pan law than what the host application may be set to by default. Most DAW's allow configuring the panning spread preference to match various consoles. In the event you want to capture SSL-style stereo response when using multiple instantiations of the SSL E Channel Strip, set the pan law preference in the host to a value of -4.5 dB.

Filters

In addition to the four-band EQ, UAD SSL E Channel Strip offers individual high and low pass filters.

When the Filter control is at minimum value (fully counter-clockwise), the filter is disabled.

The control ranges and sonics of these filters can be changed between "Black" and "Brown" modes with the EQ Type switch. See

"EQ Type" on page 490 for more information.

High Pass

The left knob determines the cutoff frequency for the high pass filter. Rotate clockwise to reduce low frequencies.

In Black mode, the slope of the high pass filter is 18 dB per octave and the available range is 16 Hz to 350 Hz. In Brown mode, the slope of the high pass filter is 12 dB per octave and the available range is 20Hz to 350 Hz.

Low Pass The right knob determines the cutoff frequency for the low pass filter. Rotate clockwise to reduce high frequencies.

In Black mode the slope of the low pass filter is 12 dB per octave and the available range is 22 kHz to 3 kHz. In Brown mode the slope of the low pass filter is 12 dB per octave and the available range is 16 kHz to 3 kHz.

Filters to Sidechain (DYN SC) This button enables the Filters sidechain function. When the Filters sidechain is active, signal output from the Filters module is removed from the audio path and is instead routed to control ("key") the dynamics module.

Sidechaining is typically used for de-essing and similar frequency-conscious techniques. To listen to the sidechain key, simply disengage DYN SC to hear the filtered signal. The sidechain dynamics/EQ implementations are true stereo when used in a stereo-in/stereo-out ("SISO") configuration.

Note: The Filters module must be active (not at minimum value) in conjunction with the Filters DYN SC button for the Filters sidechain to function. An additional dynamics sidechain is available in the EQ section ("EQ to Sidechain (DYN SC)" on page 493).

Dynamics

Separate "soft-knee" compressor/limiter and expansion/gate modules are available in the dynamics section. Each module has their own set of controls.

Important: Dynamics are not processed unless enabled by the Dynamics selector buttons ("Dynamics In (DYN IN)" on page 489).

Compressor/Limiter

Link

When UAD SSL E Channel Strip is used in a stereo-in/stereo-out configuration, two separate dynamics processors are active (one for each stereo channel). When Link is engaged, the two compressors are constrained so that they both compress by the same amount at any instant.

This prevents transients which appear only on one channel from shifting the stereo image of the output. Any big transient on either channel will cause both channels to compress.

Link is active when the button LED is illuminated. When the plug-in is used in a mono-input configuration, Link has no affect.

Compress Ratio Ratio defines the amount of gain reduction to be processed by the compressor. For example, a value of 2 (expressed as a 2:1 ratio) reduces the signal above the threshold by half, with an input signal of 20 dB being attenuated to 10 dB.

The UAD SSL E Channel Strip compressor offers a continuously variable ratio between 1:1 (no compression) and infinity:1 (limiting).

Note: Signals must exceed the Threshold value before they are attenuated by the Ratio amount.

Compress Threshold

Threshold defines the signal level at which the onset of compression occurs. Incoming signals that exceed this level are compressed. Signals below the level are unaffected.

The available range is +10 dB to -20 dB. Rotate the control clockwise for more compression.

This compressor has an automatic make-up gain function. As Threshold is lowered and compression increases (as knob is rotated clockwise), output gain from the module is increased automatically to compensate.

Compress Release

Release sets the amount of time it takes for gain reduction to cease once the input signal drops below the threshold level. Longer release times can smooth the transition that occurs when the signal dips below the threshold, which is especially useful for material with frequent peaks. However, if you set the Release time too long, the gain reduction imposed by loud sec-

tions of audio may initially reduce the level of subsequent sections of audio with lower signals.

Available Release times are continuously variable between 0.1 seconds and 4 seconds.

Compress Attack Attack defines the duration between the input signal reaching the threshold and processing being applied by the compressor. Attack time is normally 30 milliseconds ("slow" mode in Controls View). When Fast Attack is enabled, attack time is 3 milliseconds.

Fast Attack is active when the "F.ATK" LED (4K: "F.ATT") is illuminated. To toggle Fast Attack, click the LED or its label text.

Gate/Expander

The gate/expander module operates in either gate or expansion mode, as determined by the Dynamics Select button. Two attack speeds and a continuously variable release time are available in both modes.

Dynamics Select

The Select button cycles through the three modes available in the gate/expander module: Expand, Gate 1, and Gate 2.

Expand (EX)

In Expand mode, the module applies downwards expansion at a fixed 1:2 ratio, with the amount of gain reduction determined by the Range control ("Expand Range" on page 488).

Gate 1 (G1)

In Gate 1 mode, signals below the Expand Threshold are attenuated by the Expand Range amount. Gate 1 is authentic to the gate mode on earlier hardware consoles.

Gate 2 (G2)

Gate 2 mode operates the same way as Gate 1, but has a different "no-chatter" response characteristic that is derived from later versions of the hardware.

Expand Threshold

Threshold defines the input level at which expansion or gating occurs. Any signals below this level are processed. Signals above the threshold are unaffected. Threshold is continuously variable from -30 dB to +10 dB.

In typical use it's best to set the threshold value to just above the noise floor of the desired signal (so the noise doesn't pass when the desired signal is not present), but below the desired signal level (so the signal passes when present).

Expand Range Range (depth) controls the difference in gain between the gated/expanded and non-gated/expanded signal. Higher values increase the attenuation of signals below the threshold. When set to zero, no gating or expansion occurs. Range is continuously variable from 0 dB to -40 dB.

Expand Release

Release sets the amount of time it takes for gate/expander processing to engage once the input signal drops below the Threshold value. The available range is 0.1ms to 4 seconds.

Slower release times can smooth the transition that occurs when the signal dips below the threshold, which is especially

useful for material with frequent peaks.

Note: Fast release times are typically only suitable for certain types of percussion and other instruments with very fast decays. Using fast settings on other sources may produce undesirable results. **Expand Attack** Attack defines the duration between the input signal reaching the threshold and processing being applied by the expander/gate. Attack time is normally auto-sensing and program dependent. When Fast Attack is enabled, attack time is 1 ms.

Fast Attack is active when the "F.ATK" LED (4K: "F.ATT") is illuminated. To toggle Fast Attack, click the LED or its label text.

Dynamics Enable

These three buttons determine the status of the dynamics processors.

Dynamics In (DYN IN)

The DYN IN button enables both the compressor/limiter and the expander/gate modules; neither module will function when DYN IN is disabled. Each dynamics module is enabled when the LED below the buttons are illuminated.

DYN IN is useful for quickly comparing the original signal dynamics to the dynamically processed signal.

Important: DYN IN must be engaged to enable compressor/limiter and/or expander/gate processing.

Expander In (EXP IN)

The EXP IN button enables the expander/gate module. The module is enabled when the EXP IN LED is illuminated. This button has no effect when DYN IN is disabled.

Compressor In (CMP IN)

The CMP IN button enables the compressor/limiter module. The module is enabled when the CMP IN LED is illuminated. This button has no effect when DYN IN is disabled.

Dynamics
MetersThe Expansion Meter uses green LED's (left column) to display the
amount of downward expansion occurring in the expander/gate
module. Higher values indicate more gain reduction.

The Compression Meter uses amber LED's (right column) to display the amount of gain attenuation occurring in the compressor/limiter module. Higher values indicate more dynamics compression. The UAD SSL E Channel Strip EQ module is divided into four frequency bands: High Frequency (HF, blue knobs), High Midrange Frequency (HMF, green knobs), Low Midrange Frequency (LMF, yellow knobs), and Low Frequency (LF, orange knobs). The high and low bands can be switched from shelving mode into bell (peak/dip) mode. The two midrange bands are fully parametric. The EQ module can be disabled altogether or routed for dynamics sidechain keying.

EQ Type

Two different types of SSL EQ are available. The EQ Type button selects between the two types, either Black or Brown. The knob color of the LF band controls changes to reflect the current setting.

The Black and Brown EQs sound different. Black is a bit

deeper due to its higher gain values, while Brown is more gentle at extreme settings.

EQ Type Background

The original E series equaliser section was the 'Brown Knob' circuit. This was standard on all early production E Series consoles. The two parametric mid-band sections feature a classic logarithmically symmetric design that ensures that the ± 3 dB up/down points retain the same musical interval from the centre frequency regardless of frequency and amplitude settings. The two shelving sections are traditional 6 dB/octave designs with an option for a fixed Q parametric response (Bell). The '02' EQ, to give it its correct name (the last two digits of the card's part number), was used on countless recordings and mixes in the early eighties.

In 1983 a new '242' EQ circuit was developed in conjunction with the legendary George Martin for the first SSL console to be installed in AIR studios. The 'Black Knob' EQ, as it became known, featured enhanced cut and boost ranges (± 18 dB instead of ± 15 dB) together with a different control law and a steeper 18dB/octave high pass filter for tighter control of low frequencies. It is this design which is retained today as the 'E-Series' EQ option of the X-Rack, Duality and AWS consoles.

High Frequency (HF) Band

HF Frequency

HF Gain

This control determines the amount by which the frequency value for the band is boosted or attenuated. The available range is ± 15 dB in both Black and Brown modes.

Tip: Click the "0" to return the Gain knob to its center position.

This control determines the band frequency to be boosted or attenuated by the band Gain setting. The available range is 1.5 kHz to 16 kHz in both Black and Brown modes.

HF Bell

The Bell button switches the HF band from shelf mode to peak/dip mode. In normal (shelf) mode, only frequencies above the frequency value are boosted or attenuated. In Bell (peak/dip) mode, frequencies above and below the frequency value are boosted or attenuated.

In Black mode, the HF Bell Q is 1.3 and in Brown mode the HF Bell Q is 0.8.

HMF Gain

High-Mid

Frequency (HMF) Band

This control determines the amount by which the frequency value for the band is boosted or attenuated. The available range is ± 15 dB in both Black and Brown modes.

Tip: Click the "0" to return the control knob to its center position.

HMF Frequency

This control determines the HMF band center frequency to be boosted or attenuated by the band

Gain setting. The available range is 0.6 kHz to 7 kHz in both Black and Brown modes.

HMF Q

The Q (bandwidth) control defines the proportion of frequencies surrounding the band center frequency to be affected by the band gain control. The filter slopes get steeper (narrower bandwidth) as the control is rotated counter-clockwise. The available range is 0.5 to 2.5 in both Black and Brown modes.

Low-Mid Frequency (LMF) Band

LMF Gain

This control determines the amount by which the frequency value for the band is boosted or attenuated. The available range is ±15 dB in both Black and Brown modes.

Tip: Click the "O" to return the control knob to its center position.

LMF Frequency

This control determines the LMF band center fre-

quency to be boosted or attenuated by the band Gain setting. The available range is 0.2 kHz to 2.5 kHz in both Black and Brown modes.

LMF Q

LF Gain

The Q (bandwidth) control defines the proportion of frequencies surrounding the band center frequency to be affected by the band gain control. The filter slopes get steeper (narrower bandwidth) as the control is rotated counter-clockwise. The available range is 0.5 to 2.5 in both Black and Brown modes.

Low Frequency (LF) Band

This control determines the amount by which the frequency value for the LF band is boosted or attenuated. The available range is ± 15 dB in both Black and Brown modes.

Tip: Click the "0" to return the control knob to its center position.

LF Frequency

This control determines the band center frequency to be boosted or attenuated by the band Gain setting. The available range is 30 Hz to 450 Hz in both Black and Brown modes.

LF Bell

The Bell button switches the LF band from shelf mode to peak/dip mode. In normal (shelf) mode, only frequencies below the frequency value are boosted or attenuated. In Bell (peak/dip) mode, frequencies below and above the frequency value are boosted or attenuated.

In Black mode, the LF Bell Q is 1.3 and the Brown mode the Bell Q is 0.8.

EQ Enable

These three buttons determine the status of the EQ module.

EQ In

enabled when the LED below the button is illuminated.

EQ to Sidechain (DYN SC)

This control enables the EQ sidechain function. When the EQ sidechain is active, signal output from the EQ module is removed from the audio path and is instead routed to control ("key") the dynamics module. The EQ sidechain is enabled when the LED below the button is illuminated.

Sidechaining is typically used for de-essing and similar frequency-conscious techniques. To listen to the sidechain key, simply disengage DYN SC to hear the equalised signal. The sidechain dynamics/EQ implementations are true stereo when used in a stereo in/stereo out ("SISO") configuration.

Note: The EQ module must be active in conjunction with the EQ DYN SC button for the EQ sidechain to function. Note there is another dynamics sidechain available in the Filters section ("Filters to Sidechain (DYN SC)" on page 485).

Pre-Dynamics (PRE DYN)

During "normal" operation (PRE DYN disengaged) the audio signal is output from the dynamics module into the EQ module. Activating PRE DYN reverses this routing, so the EQ is ahead of the dynamics module instead. Pre-dynamics is active when the LED below the button is illuminated.

Global

I/O Meters

The vertical LED-style metering provides a visual indication of the signal levels at the input and output of the plug-in (the meters are not calibrated).

The input meter is the left LED column and the output meter is the right LED column.

Note: Each meter column represents the sum of the left and right channels (it is not a stereo meter).

Input

Input controls the signal level at the input to the plug-in. The default value is 0 dB. The available range is ±20 dB. Increasing the input may result in more compression, depending on the values of the Threshold and Ratio parameters.

Tip: Click the "0" to return the control knob to its center position.

Output Output controls the signal level that is output from the plug-in. The default value is 0 dB. The available range is ±20 dB.

0 -20 +20 OUTPUT

Tip: Click the "0" to return the control knob to its center position.

Phase (Ø) The Phase (Ø) button inverts the polarity of the signal. The signal is inverted when the button is depressed. Leave the button out for normal polarity.

PowerThe Power button determines whether the plug-in is active.Click the Power button to disable the processor. Power is useful
for comparing the processed sound to that of the original sig-
nal.

Usage Notes

The SSL E Series channel has been used to mix more hit records than any other in history. Its no-nonsense feature and control set make it easy to get the sound you're looking for.

A useful approach to getting to know the SSL E is to start with a fresh mix, where little to no EQ or dynamic mixing has been done yet. Even better, start you mix with the SSL G Bus Comp on the master fader as well, which will give you the complete SSL sound. For an even more authentic SSL experience, adjust your DAW's default pan rule (usually +3) to SSL's custom +4.5 rule.

There are two four-band (LF, LMF, HMF HF) EQ options on the SSL E, known as "brown" and "black". It is important to note that while only the LF bass knobs change color when switching EQ's, ALL bands are affected.

Brown is the original SSL design, with gentler Q, and smaller gain and frequency ranges. It is the easier of the two to easily get a good, musical sound. LC and HC filtering is a gentle 12 dB. Brown is the recommended starting place for those unfamiliar with SSL. The black EQ is a later design, with the option for narrower Q and broader gain and frequency ranges, making it more useful for fixative EQ as sweetening. The black EQ design changes were recommended by famed Beatles producer George Martin. Each band is different from the brown design, plus the The LC is a steeper 18 dB per octave. The normal arrangement is dynamics first, but the EQ can be put as the first process with the "PRE DYN" (Pre Dynamics) button.

It is interesting to note that the console labels did not change on the consoles moving from the ± 15 dB gain range to the ± 18 dB of the black EQ, nor did the frequency or Q labels.

The gain section has remained largely the same on SSL consoles from the beginning until now, with dedicated VCA compressor and expand/gate circuits. The compressor's simple control set allows for a wide variety dynamics control, from transparent to aggressive. A fully continuous ratio allows for the full range of knee from very gentle to fully limited. A fixed two position attack and the continuously adjustable release are perfect control sets for general console dynamics control. it is interesting to note that at heavy compression with quick release times, the SSL design has a similar room-expanding quality as the 1176 on things like drums and room mics.

While gates are not as relevant in the DAW as they once were for analog mixing, the SSL has one of the most transparent and musical console gates available, which can be used for fixative or creative purposes. There are two gate modes, G1 is the original E series gate response, with G2 has a minimal chatter response borrowed from the later G series gate. The "DYN SC" (Dynamic Sidechain) button allows the user to create frequency dependent gain reduction arrangements with either the Compressor or Gate/expander.

CHAPTER 50 SSL G Bus Compressor

Large Format Console Dynamics

The SSL G Series Bus Compressor plug-in for UAD-2 is an incredibly faithful circuit emulation of the legendary SSL 4000 G console's bus compressor. The undeniable drive and punch of this G Series master compressor — modeled to exacting detail by Universal Audio and fully authenticated by Solid State Logic® — helped make the original 4000 G Series the world's most successful studio production console. Engineers have come to rely on this master compressor to "glue together" mixes like nothing else, as well as patching into it for wonderful results on drums, pianos and more.

With simple, intuitive controls and transparent compression characteristics, the G Series Bus Compressor plug-in for UAD-2 captures the iconic SSL sound with stunning accuracy. Plug-in controls comprise fixed Compression Ratios (2:1, 4:1 and 10:1), and Attack and Release controls with program-dependent Auto Release function. Continuous Threshold Control and Make-Up Gain, compressor bypass, and the original Auto Fade (1-60 seconds) feature provide full operational authenticity.

SSL G Bus Compressor Screenshot

Figure 154. The SSL G and 4K Bus Compressor plug-in windows

SSL G Bus Compressor Controls

Threshold	Threshold defines the signal level at which the onset of compression occurs. Incoming signals that exceed this level are compressed. Signals below the level are unaffected. The control range is ± 15 dB.
	As the Threshold control is decreased and more compression occurs, output level is typically reduced. Adjust the Make Up control to modify the output to compensate if desired.
Make Up	Make Up controls the signal level that is output from the plug-in. The range is 0 dB to +15 dB.
	Generally speaking, adjust the Make Up control after the desired amount of compression is achieved with the Threshold and Ratio controls. Make Up does not affect the amount of compression.
Attack	Attack sets the amount of time that must elapse once the input signal reaches the Threshold level before compression is applied. The faster the Attack, the more rapidly compression is applied to signals above the threshold. Avail- able Attack times are discrete values of 0.1ms, 0.3ms, 1ms, 3ms, 10ms, and 30ms.
	The availability of relatively slow attack times (as compared to other compres- sors) is one factor that can provide the in-your-face-pumping quality that is so popular with large console VCA-style compressors.
Release	Release sets the amount of time it takes for compression to cease once the in- put signal drops below the threshold level. Slower release times can smooth the transition that occurs when the signal dips below the threshold, especially useful for material with frequent peaks. However, if you set the Release time too long, compression for sections of audio with loud signals may extend to lengthy sections of audio with lower signals.

Available Release times are discrete values of 100ms, 300ms, 600ms, 1.2s, and Auto. The Auto release characteristic for SSL G Bus Compressor has a unique quality that is optimized for program material.

Ratio Ratio defines the amount of gain reduction to be processed by the compressor. For example, a value of 2 (expressed as a 2:1 ratio) reduces the signal above the threshold by half, with an input signal of 20 dB being reduced to 10 dB. The

available Ratio values are 2:1, 4:1, and 10:1.

Power (IN) The Power button determines whether the plug-in is active. Click the Power button to toggle the processor state. Power is useful for comparing the processed sound to that of the original signal.

Gain Reduction Meter

The Gain Reduction VU-style meter displays the amount of gain reduction occurring in the compressor. Higher values indicate more gain reduction.

Increase the signal level into the plug-in and/or lower the Threshold control to increase gain reduction.

Fade

The SSL G Bus Compressor provides a Fade function that, upon activation, automatically reduces the plug-in output to minimum within a specified time period. This function enables extremely smooth-sounding fade outs

(and fade ins), plus it can be automated as well.

The Fade function processes the signal at the output of the compressor. The fade signal level that is output has an exponential curve.

Fade Rate	Fade Rate determines the amount of time that will pass between the Fade but- ton being activated and the plug-in output level being reduced to minimum (or being raised to 0 dB in the case of a fade in). The available range is from 1.0 second to 60 seconds.
	Fade times immediately reflect the current Fade Rate value. Therefore a fade out that has already been initiated can be accelerated by changing Fade Rate during the fade out. Conversely, a fade in can be accelerated by changing Fade Rate during the fade in.
Auto Fade Button	Activating the Auto Fade button initiates a fade out. The fade out time is de- termined by the Fade Rate parameter. The Fade button blinks when a fade out is in progress, and is continuously lit when the fade out is complete (when the Fade Rate time has elapsed).
	Deactivating Fade (clicking the solid-lit button) initiates a fade in. During a fade in, the signal level is increased from the current level of attenuation to 0 dB of attenuation. The Fade button flashes when a fade in is in progress, and is no longer illuminated when the fade in is complete (when the Fade Rate time has elapsed).
	Toggling the Fade button causes an already active fade to reverse direction, without a jump in output level. The Fade Rate is constant even if an active fade is interrupted. For example: If the Fade Rate value is 30 seconds and a fade out is initiated, then Fade is clicked again after 20 seconds, it will take 20 sec- onds to fade back in.
	Tip: Shift+click the Fade button to instantly return the level back to 0 dB (this feature cannot be automated).

General Usage Notes

The SSL G Bus compressor has been used to put the final touch of cohesiveness or "glue" to more mixes than any other compressor in history! Its true usefulness and beauty is usually in its subtle ability to make your mix "pop" just a little more, with a subtle increase in energy and excitement.

The SSL G is designed with the 2-bus in mind, and the control set adjusts the L/R simultaneously. The ratios, attack and release settings are also specially tailored for bus use, and give just the right variety of options to make it useful for a wide variety of source material. Attack and release times allow the compression behavior to be 'tuned' to the tempo and feel of the song to some de-

gree, and the "Auto" setting provides a program-dependent, multi-stage release for the greatest degree of transparency. Use the 2:1 for the most transparent sound and 10:1 for tougher, more audible sound, or 4:1 for in between. Usually, this processor is meant to be used with minimal gain reduction. In most cases, setting the threshold for 1-2 dB average gain reduction is most common, with occasional transients that go beyond the average. In quieter passages little or no meter movement will occur. Use make up gain to get a good gain match between active and bypassed.

Traditionally, the SSLG is most commonly used from the beginning of the mix process, and the engineer is "mixing to" the sound and behavior of the compressor. The ideal way to audition this plugin is on a new mix, dropped into an insert on your stereo master fader. In this case, you will be spending a lot of time keeping an eye on gain reduction metering and you may make tweaks to the setup as the mix progresses. Of course it can also be dropped in existing mixes at any time, but keep in mind it may take a bit more effort to dial in, especially if your ear is already used to the sound without its compression properties.

The SSL G is also useful of groups, such as drum busses. in this case, a more aggressive approach may be appropriate, with a greater range of gain reduction. 10:1 will give a harder sound often desired for drum groups. Fast attacks releases will give the most audible sound of the compressor working.

Finally Auto Fade is useful when the end of a song needs a gradual decrease in volume. The speed of the fade can be tuned from 1 to 60 seconds, and incorporates SSL's unique fade curves. fade in is also available.

Studer A800

Multichannel Tape Recorder

For more than 30 years, artists and engineers alike have been drawn to the warm sound, solid "punchy" low-end, and overall presence of the Studer® A800 Multichannel Tape Recorder. The sheer number of albums recorded on this legendary 2" analog tape machine — including classics from Metallica, Stevie Wonder, Tom Petty and Jeff Buckley — serve as shining examples of the musicality of analog tape.

Authenticated by Studer, and modeled by UA's world-renowned team of DSP engineers and AES magnetic recording expert Jay McKnight over a 12-month period, the Studer A800 Multi-Channel Tape Recorder plug-in for UAD-2 is the first and only product of its kind. This plug-in faithfully models the entire multitrack tape circuit path and electronics of an A800 machine — plus the distinct sounds of multiple tape formulas. Put simply, it's the world's most accurate representation of professional analog tape recording, now available on Mac and PC.

As the first microprocessor-controlled tape machine, the Studer A800 marked a new generation of professional multitrack recorders when it was introduced in 1978. Years ahead of its time, the A800 remains a sonic benchmark, and can still be found in studios all over the planet. However, with their massive steel frame and meter bridge, twin half-horsepower motors and cast alloy deck plates, original A800 units tip the scales at a backbreaking 900 pounds (408 kg) — not to mention the space required to house such a device. The UAD-2 plug-in version poses none of the hardware hassles of manual calibration and maintenance, nor the potential for tape degradation — while retaining all the beautiful sonic qualities that make tape such a beloved recording medium. Just drop the A800 in your first insert on every track desired, and enjoy the benefits of having recorded to tape.

All visual and aural references to Studer products and all use of Studer trademarks are being made with written permission from Harman International Industries, Inc. Any references to third party tape formulations are used solely for identification and do not imply any endorsement by, or affiliation with, any tape manufacturer.

Studer A800 Screenshot

Figure 155. The Studer A800 plug-in window

Operational Overview

The Studer A800 for UAD-2 provides all of the original unit's desirable analog sweetness; like magnetic tape, users can dial in a clean sound, or just the right amount of harmonic saturation using the Input and Output controls. The reel deck IPS control steps through the three tape speed choices available on the original hardware (7.5, 15, or 30 IPS), each with distinct frequency shift, head bump and distortion characteristics. The Tape Type control lets users choose from four of the most popular magnetic tape formulas of the last three decades, each with their own subtle sonic variation and tape compression characteristics. The Cal control allows the user to choose between +3dB, +6dB, +7.5dB, or +9dB calibration levels, which can be used at their recommended settings, or tweaked for additional tonal options. Input, Sync and Repro paths, plus Thru (bypass) are available for authenticity, providing all available circuit options of the A800. A huge time saver, the Studer A800 plug-in features an innovative Gang Controls setting, allowing for instant global adjustment of any parameters for all Studer A800 instances in your session.

Secondary controls are hidden behind the reel deck, and can be exposed by clicking on the Studer badge or Open label of the plug-in GUI. The Equaliser control allows the user to select between the American (NAB) and European (CCIR) standardized EQs, providing regional pre-emphasis/de-emphasis filtering at 7.5 and 15 IPS, each with its own sonic qualities — plus the AES EQ at 30 IPS. The HF Bias calibration parameter allows the user to tune the HF oscillation voltage feed to the magnetic record head, striking a balance between record sensitivity and distortion. This can also be used creatively as an effect — from warm, overbiased sounds, to voltage-starved distortion and chatter. HF Record is a calibration filter that allows for HF makeup when the ideal Bias leaves a high frequency deficiency; both HF Bias and HF record are fed into the tape nonlinearity. Sync and Repro HF and LF calibration EQs allow for adjusting for a flat playback response, or can also be used creatively. All Secondary Controls (page 509) can be automatically calibrated to the manufacturer's recommended settings via the A800's Auto Cal feature, or may be disabled. Finally, separate controls for Hiss and Hum are available - each tuned to default settings to match the hardware behavior - with a global noise bypass option.

Multitrack Tape Machine The primary purpose of Studer A800 is to obtain multichannel tape sonics within the DAW environment. To obtain the classic multitrack tape sound, the plug-in should be placed as the first insert on individual tracks, before other processing is applied. Creative "non-standard" results can be obtained by placing the Studer A800 in subsequent inserts after other processors or on busses in a send/return configuration. Mixdown to two tracks can be emulated by placing the plug-in on the stereo output bus.
Primary & Secondary Controls The primary controls (those that are typically most used) are on the main panel at the bottom portion of the interface. Additional (typically less used) controls are available on the secondary panel. The secondary panel (see Figure 156) is accessed by clicking the Studer A800 label or the "OPEN" text label above it.

For detailed descriptions of the parameters, see "Primary Controls" on page 506 and "Secondary Controls" on page 509.

Figure 156. The Studer A800 plug-in window with exposed secondary controls

Ganged Operation The UAD Studer A800 implements a control ganging feature that allows easy simultaneous parameter modification for all instances of the plug-in. The feature enables the DAW to emulate the multitrack tape deck scenario more accurately, where a single change to some multitrack machine parameters (such as tape speed, formula, and calibration settings) would affect all tape channels. See "Gang Controls" on page 511 for details.

Mono/Stereo
OperationThe UAD Studer A800 is designed with a single-channel interface, to emulate
the individual channels of a multitrack tape recorder. However, when the
plug-in is used on a stereo track, the "mono" controls affect both channels of
the stereo signal identically.

Primary Controls

Path SelectThe Path Select buttons specify which of
the four possible signal paths is active
in the A800. The active mode is indi-
cated by an illuminated button.

Thru

Thru is a bypass control. When enabled, emulation processing is disabled and DSP usage is reduced. Thru is useful for comparing the processed settings to the original signal. Thru is identical to the OFF position in the IPS control (page 508).

Note: DSP usage is reduced only when DSP LoadLock is disabled. If DSP LoadLock is enabled (the default setting), activating Thru will not reduce DSP usage.

Input

Input mode emulates the sound of the A800 through the machine electronics only, without tape sonics. This is the scenario when the machine is in live monitoring mode but the tape transport is not running.

Sync

Sync mode models the sound of direct recording and playback via the sync/record head, plus all corresponding machine electronics.

Repro

Repro mode models the sound of recording through the record head and playback through the reproduction head, plus all corresponding electronics.

Tape Type

Tape Type selects the active tape stock formulation. Four of the most popular 2" magnetic tape formulas are modeled in the A800 plug-in: 250, 456, 900, and GP9. Each type has its own subtle sonic variation, distortion onset, and "tape compression" characteristics.

Generally speaking, the lower the Cal Level for each formula, the higher the signal level required to reach saturation and distortion.

Cal Level Cal Level automatically sets tape calibration/fluxivity. The Cal Level setting takes care of the setup one would need to make under equivalent hardware operation, and sets the reference tape/flux level without disturbing the (unity) gain of the plug-in.

The record, repro, and sync gain trims found on the A800

channel cards are not present on the plug-in. Instead (when "Auto Cal" on page 511 is enabled), these controls are amalgamated into this single Cal Level gain control.

As tape formulas advanced, their output level increased, thus lowering relative noise floor. +3, +6 and +9dB output formulas were available in the 2" format. Under normal use, the machine would be calibrated to the tape's output level. However, users would sometimes under-calibrate to leave more headroom for a broader sweet or to prevent electronics from clipping. Therefore, the user can go traditional and calibrate to the recommended levels, or select a non-corresponding calibration setting with Cal Level.

As an example, if 456 is the selected Tape Type and when Cal Level is set at +6 (6 dB higher than the NAB tape standard), the reference fluxivity level is 355 nW/m (nanoweber per meter) and is 10 dB below the point where THD reaches 3% (referred to as the maximum operating level). Therefore, with a 1kHz test tone at -12dBFS sent to the plug-in, with Tape Type set to 456, Cal Level set to +6, and Auto Cal enabled, output levels of the plug-in will match the input level and fluxivity on the tape will be 355 nW/m.

The manufacturer's recommended calibration settings for each Tape Type are as follows:

- 250: +3 Calibration (251 nWb/m)
- 456: +6 Calibration (355 nWb/m)
- 900: +9 Calibration (502 nWb/m)
- GP9: +9 Calibration (502 nWb/m)

Note: The noise floor is affected by Cal Level when Noise Enable (page 510) is active.

Tip: The UAD Studer A800 default bank offers a variety of preset Tape Type, Tape Speed, CAL level, and EQ configurations that are commonly used for the recording of specific genres.

IPS (Tape Speed)

The IPS (Inches Per Second) control determines the speed of the tape transport and the associated "head bump."

(Head bump is bass frequency build-up that occurs with magnetic tape; the dominant frequencies shift according to transport speed.)

15 IPS is considered the favorite for rock and acoustic music due to its low frequency "head bump" (low frequency rise) and warmer sound, while 30 IPS is the norm for classical and jazz due to its lower noise floor, greater fidelity and flatter response. 7.5 IPS is also available for an even more colored experience, with even greater frequency shift.

Tip: Click on the "IPS" text label to stop/start the spinning reels animation.

The OFF position is a bypass control. When set to OFF, emulation processing is disabled, the VU Meter and control LEDs are dimmed, and DSP usage is reduced. OFF is useful for comparing the processed settings to the original signal. OFF is identical to the Thru position in the Path Select control (page 506).

Note: DSP usage is reduced only when DSP LoadLock is disabled. If DSP LoadLock is enabled (the default setting), activating OFF will not reduce DSP usage.

Input Input acts as an outside gain control (like an external console fader), and adjusts the signal level going into the tape circuitry. The available range is -12 dB to +24 dB.

Just like real magnetic tape, lower Input levels will have a cleaner sound, while higher levels result in more harmonic saturation and coloration.

Higher Input levels will also increase the output level from the plug-in. The Output control can be lowered to compensate.

Tip: Click the "0" control label text to return to the Input value to 0.

Output

Output acts as an outside gain control (like an external console fader) and adjusts the gain at the output of the plug-in. The available range is -24 dB to +12 dB.

Tip: Click the "0" control label text to return to the Output value to 0.

VU Meter The VU Meter provides a visual representation of the signal levels after the virtual tape. The Input control affects how "hot" the signal is.

Higher VU levels typically indicate more harmonic

saturation, coloration, and/or distortion. However, this will depend on the other control values.

The plug-in operates at an internal level of -12 dBFS. Therefore a digital signal with a level of -12 dB below full scale digital (0 dBFS) at the plug-in input will equate to 0 dB on the plug-in meters.

Secondary Controls

The Secondary Controls are exposed by clicking the "Studer A800" label or the "OPEN" text above it. See Figure 156 and "Primary & Secondary Controls" on page 505 for more information.

Tip: The last-used state of the Secondary Controls panel (open or closed) is retained when a new Studer A800 plug-in is instantiated.

The state of the panel (open or closed) settings retained with new plug-in instantiations.

Equaliser (Emphasis EQ)

The Equaliser buttons determine the active Emphasis EQ values and the frequency of the hum noise. Click the equaliser buttons to alternate between the two different types.

NAB or CCIR curves can be selected when the Tape Speed is 7.5 or 15 IPS. When the Tape Speed is 30 IPS, neither value

is available (the LEDs are dimmed) because the EQ is fixed with the AES emphasis curve.

When the value is set to NAB, the Hum Noise frequency is 60 Hz (the United States standard). When set to CCIR, the Hum Noise frequency is 50 Hz (the standard in Europe and other regions). See "Noise Enable" on page 510 and "Hum Noise" on page 515 for more information about Hum.

Note: When IPS (Tape Speed) is set to 30 IPS, the yellow LEDs are not illuminated, indicating that the Emphasis EQ is set to AES. However, in 30 IPS mode, the Equaliser switch can still be changed to set the frequency of Hum Noise.

Tape Speed and Emphasis EQ were originally practical controls for record duration vs. noise and local standards. It is important to note that historically, the origin of the tape machine (US or European) dictated the built-in EQ emphasis, but later machines like the A800 had both circuits available.

While the hardware A800 has discrete controls for tape speed and emphasis EQ, the user has to recalibrate the machine for various speeds and re-jumper the whole machine for 30/15 or 15/7.5 IPS usage. The A800 plug-in has three speeds and related EQ pre-emphasis/de-emphasis filtering, presented as two easy to use controls for simple auditioning of the sonic variations.

CCIR (also known as IEC) is the EQ pre-emphasis made famous on British records and is considered the technically superior EQ; many say this EQ was part of the "British sound" during tape's heyday. NAB (also referred to as IEC2) was the American standard with its own sound. AES is truly standard-ized for 30 IPS and is the sole EQ found on the Studer A800 for 30 IPS.

Noise Enable

The Noise Enable buttons are a global enable/disable control for the individual hum and hiss components of the A800 model. The amount of hum and hiss noises are continuously variable and are set with the Hum Noise and Hiss Noise controls (page 514). Click the Noise buttons to alternate between OFF and ON. While noise is historically considered a negative, and was the attribute that pushed the technical envelope for better machines and formulas, noise is still an ever-present component of the sound of using tape and tape machines.

Auto Cal The Studer A800 has individual parameters for Bias, HF Record EQ, and Sync/Repro EQ. On the hardware tape machine, these calibration controls are usually adjusted whenever Tape Type, Tape Speed, or Emphasis EQ is changed.

When Auto Cal (Automatic Calibration) is ON in the plug-in,

these calibration controls (see Figure 157 on page 513) are automatically adjusted to the calibrated values whenever the Tape Type, Tape Speed, and Emphasis EQ are modified. After Auto Calibration occurs, the automatically adjusted parameters can then be modified to any value if desired.

When Auto Cal is OFF, the calibration parameters do not change values when Tape Type, Tape Speed, and Emphasis EQ are modified.

Note: Auto Cal is enabled by default.

Tip: When making manual calibration settings, consider disabling Auto Cal so the manually calibrated settings are not accidentally lost if another control is modified.

Gang Controls

Gang Controls enables global control adjustments of all parameters for all Studer A800 instantiations. This functionality may be accessed from within any active Studer A800 plug-in.

Click the Gang Controls buttons to alternate between the two

states. A red flashing LED is present whenever Gang Controls is enabled as a reminder to use this feature with caution.

Important: When Gang Controls is ON and a Studer A800 parameter is modified, the current value of that parameter on all other Studer A800 instantiations will be overwritten and cannot be recovered.

Gang Controls Notes

• Gang Controls is a read-only, non-automatable parameter and its current value is not saved with the session.

- Gang Controls is a static control without the ability to make relative offsets. Disable Gang Controls if offsets between the same control within different instantiations is desired.
- If Gang Controls is enabled when Auto Cal is enabled, any adjustments made to Tape Type, Tape Speed or Emphasis EQ causes the Calibration Controls to be automatically adjusted for all instantiations. However, if the Tape Type, Tape Speed or Emphasis EQ values do not already match between instantiations before Gang Controls is active, the resulting calibrated values may not match either.
- When Gang Controls is enabled, there are no audible or visual changes to the other Studer A800 instantiations until a control is actually changed.
- When Gang Controls is enabled and a Studer A800 settings preset is loaded via the UAD Toolbar, the loaded parameter settings are pushed to all Studer A800 instances.

Calibration
ControlsRefer to Figure 157 on page 513 for the HF Record EQ, Bias, Sync EQ, and
Repro EQ controls. These controls are automatically adjusted when Auto Cal
is active, or they can be manually modified as desired.

The "flat" calibrated position for these controls is determined by Tape Type and Tape Speed; therefore the available \pm range for these controls is dependent on the current calibration.

Tip: Clicking the text label for any of the HF Record EQ, Bias, and Sync/Repro EQ controls will return that parameter to the calibrated value.

Note: When making manual calibration settings, consider disabling Auto Cal (page 511) so the manually calibrated settings are not accidentally lost if another control is modified.

Figure 157. The calibration controls for Studer A800

HF Record EQ HF (High Frequency) Record EQ is provided to make up for common residual HF loss due to Bias optimization and system filtering. It is used to tune HF content into the incoming signal prior to the tape non-linearity. The control provides a continuous "boost filter" gain and affects saturation characteristics.

Note: This filter is prior to the tape record circuit, while the other EQs (Sync, Repro) are for tape playback only.

- **HF Driver Bias** Bias is defined as an oscillator beyond the audible range applied to the audio at the record head, allowing for adjustment of the record behavior. Ideal bias voltage settings provide maximum record sensitivity and low distortion. Intentionally overbiasing is a common technique especially for "tape compression" of drums, giving a warmer, gently saturated sound. Underbiasing can also be used to add distortion and other nonlinear responses, similar to gate chatter or cold solder joints; extremely low voltages may even cause audio to drop out entirely. Bias voltage, HF Record EQ, and fixed Emphasis EQ (CCIR, NAB, AES) work together to provide a linear response to the recorded signal.
- **Sync/Repro EQ** Sync and Repro Playback EQ Controls are available for tape playback calibration. They affect the signal coming out of the tape circuitry.

With the hardware machine, these controls enable compensation for any tape frequency loss or head wear. Under hardware use, the Sync and Repro playback heads are calibrated to normal operating standards and are nearly identical when set correctly. However, they may be tuned incorrectly to achieve a desired sound. Sync EQ and Repro EQ are used as filters to shape the frequency response of the system in maintaining a flat response, but they may be used on their own for high or low frequency adjustment.

Sync HF EQ

Adjusts the high frequency content when Path Select (page 506) is set to Sync. When Path Select is not set to Sync, the control has no effect.

Sync LF EQ

Adjusts the low frequency content when Path Select (page 506) is set to Sync. When Path Select is not set to Sync, the control has no effect.

Repro HF EQ

Adjusts the high frequency content when Path Select (page 506) is set to Repro. When Path Select is not set to Repro, the control has no effect.

Repro LF EQ

Adjusts the low frequency content when Path Select (page 506) is set to Repro. When Path Select is not set to Repro, the control has no effect.

Noise

The Noise controls allow the user to control the Hum and Hiss elements found on the original hardware. Separate controls for Hum and Hiss are available and each can be adjusted for creative purposes.

Tip: Click the control label text to return to the Hum or Hiss value to 0.

Hiss affects the signal at the tape head; Hum is added after the tape circuitry. Hum and Hiss values default to comparative levels found on the original hardware. The available range for

both controls is ± 25 dB.

The global Noise Enable control (page 510) must be ON for the Hum and Hiss parameters to have any effect.

Hum Noise

The Hum Noise frequency is dependent on the setting of the Equaliser (Emphasis EQ) control (page 510). The frequency is 60 Hz when set to NAB (US) and 50 Hz when set to CCIR (European).

Note: When IPS (Tape Speed) is set to 30 IPS, the yellow Equaliser (Emphasis EQ) LEDs are not illuminated, indicating that the Emphasis EQ is set to AES. However, in 30 IPS mode, the Equaliser switch can still be changed to set the frequency of Hum Noise.

Hiss Noise

Just like the hardware, the amount of hiss is dependent on settings of the various controls. Overall Hiss Noise is set with this control, but may change based on the Path Select, Tape Speed, Tape Type, Emphasis EQ, Cal Level, Bias, Playback EQs, and Output Level controls.

Because hiss noise is an element of t ape playback, Hiss is disabled when Path Select is to INPUT.

Note: Hiss timbre and level can change with Tape Type.

Studer A800 Latency

The Studer A800 uses an internal upsampling technique. This upsampling results in a slightly larger latency than most other UAD plug-ins. See "Upsampled Plug-Ins" on page 563 for more information.

CHAPTER 52

Teletronix LA-2A Leveler Collection

History

For 50 years, the original and most revered and relied upon transparent optical gain reduction design

The Teletronix LA-2A Leveling Amplifier rivals only the Universal Audio 1176 as the most ubiquitous outboard processor on the planet, and is considered the most revered and relied upon vocal compressor in history. With its transparent, program dependent optical compression and meticulously designed tube amplifier, Teletronix Levelers instantly became favored for studio and broadcast use. Teletronix founder Jim Lawrence first used photocells for controlling gain in the early 60s. His ingenious optical compression design was a technological breakthrough surpassing the stability and transparency of earlier tube detector circuits. M.T. "Bill" Putnam later bought this patented technology and continued the manufacturing of the Teletronix LA-2A and its follow-up products for years to come. Universal Audio still hand makes this point-to-point, tube-amplified studio staple, including the LA-2A's all-important T4 electro-luminescent gain reduction cell. 50 years later, the Teletronix LA-2A is still the workhorse compressor and the most transparently musical method to control dynamics.

Like with the 1176 Classic Limiter Collection's redesign from UA's legacy 2001 UAD-1 plug-in, advances afforded by greater processing power and over a decade of emulation experience gave the team at Universal Audio the latitude to upgrade the LA-2A in luxurious, obsessive detail. From improvements to the time constant fit methods and gain reduction nonlinearities, to the addition of the transformer and tube amplifier distortion behaviors, the resulting effort furthers UA's position as having the most authentic, in-the-box optical compression tools on the market. Universal Audio is the only company with access to the original T4's highly-guarded chemical and manufacturing formula, and thus the only company with the ability to study the staggeringly complex interactions of the unique photoresistor and luminescent light source behaviors down to the quantum level. For discerning professionals, trust only the tools bearing the original Teletronix name.

Teletronix LA-2A Leveler Collection Screenshots

Figure 158. The Teletronix LA-2A Silver plug-in window

Figure 159. The Teletronix LA-2A Gray plug-in window

Figure 160. The Teletronix LA-2 plug-in window

Figure 161. The Teletronix LA-2A Legacy plug-in window

LA-2A Plug-In Family

The complete LA-2A family is comprised of four individual plug-ins, as seen on the previous page. Each variation has its own unique sonic characteristics.

Teletronix LA-2AThe Teletronix LA-2A Leveler Collection (introduced in UAD v6.5) provides access to three historical and highly coveted revisions in the Teletronix product
line.

The newer state-of-the-art algorithms in this bundle take full advantage of the extra power available on UAD-2 devices and the design sophistication and expertise gained since the introduction of the legacy LA-2A plug-in in 2001.

Teletronix LA-2A Silver

The LA-2A "Silver" captures the North Hollywood, California unit manufactured in the late 1960s by Bill Putnam, with its brushed aluminum panel and original T4B gain reduction module. Perhaps the most flexible of the three plug-ins in the collection, this unit's fast time constant makes it suitable on the widest variety of program material, including transient-rich sources like drums and percussion.

Teletronix LA-2A Gray

The LA-2A "Gray" covers Jim Lawrence's original mid-1960s painted unit from Pasadena, California. This unit maintains an average time constant, covering the gamut of medium speed compression uses.

Teletronix LA-2

The LA-2 captures one of the earliest Teletronix examples. This exceedingly rare unit preceded the LA-2A by a few years and incredibly, still has the original T4A fully intact. The LA-2 provides the slowest response and a unique "mellowed" sound due to 50 years of luminescent panel aging inside the T4 module. Use the LA-2 with legato tempos and your most vowel-like sources for a transparency and sublime mood unlike any other compressor.

Teletronix LA-2A Legacy The Teletronix LA-2A Legacy plug-in (Figure 161 on page 517) was, along with the UA 1176LN Legacy, the first plug-in available for the UAD platform. This first-generation plug-in runs on UAD-1 and UAD-2 devices. It still has a great sound and is very usable, especially when there are not enough DSP resources to use the second-generation models in the newer Teletronix LA-2A Leveler Collection.

To accommodate the limited DSP resources of the UAD-1, the transformer and I/O distortion characteristics were not modeled in this plug-in. This makes the Teletronix LA-2A Legacy especially useful in situations where less distortion, and less DSP usage, is desirable.

Operational Overview

Applications In the 60s and 70s, the LA-2A and 1176 became inextricably linked as the must-have dynamic tools of the day. If the 1176 is to the Stratocaster in terms of immediacy and flexibility, then the LA-2A is to the Gibson Les Paul in terms of warmth and one-of-a-kind, magical sonic distinction. An important characteristic of the T4 photocell response is that it is both program and frequency dependent. The T4 cell has a multi-stage release, and can take a few minutes to fully recover from the incoming signal.

The primary use is as individual inserts for sources that require nominal transparent gain reduction, such as vocals, bass, strings or horns. These tools can also be used to isolate the "color" of the output amplifier by turning off the Peak Reduction control, even to extreme distortion settings. An interesting sidechain distortion can be achieved at the most extreme Peak Reduction settings, which primarily affects low frequencies.

- **Parameters** No compressor is as easy to operate or instantly satisfying to use as the Teletronix Levelers. Peak Reduction applies the compression threshold to the incoming signal up to -40 dB, while Gain amplifies the signal for level matching post Peak Reduction. Set the metering view on any of the units with either +4 or +10 dB Output Gain, or Gain Reduction. Both LA-2A Gray and Silver expose the hardware's rear Limit/Compress switch, as well as the unit's "R37 FM Broadcast Emphasis" filter as front panel parameters. Although not present on the unit originally, the LA-2 was "hot-rodded" to include Emphasis, which is exposed on the front panel. Lastly, Power bypasses all DSP processing, providing a handy level matching tool not found on the original hardware.
- Artist Presets The Teletronix LA-2A Leveler Collection includes artist presets from prominent LA-2A users. The artist presets are in the internal factory bank and are accessed via the host application's preset menu. The artist presets are also copied to disk by the UAD installer so they can be used within Apollo's Console application. The presets can be loaded using the Settings menu in the UAD Toolbar (see "Using UAD Powered Plug-Ins" in Chapter 7 of the UAD System Manual).

Note: Presets created with the original LA-2A Legacy plug-in are incompatible with the newer Leveler Collection plug-ins.

Reference Level
Plug-ins in the Teletronix LA-2A Leveler Collection operate at an internal reference level of –12 dBFS. This enables more range in the primary controls (Peak Reduction and Gain) before the I/O distortion characteristics become apparent (signals at the input of these plug-ins can be pushed higher before they distort).
For additional information about internal reference levels, see "Operating Levels" in Chapter 7 of the UAD System Manual.

Upsampling The Teletronix LA-2A Leveler Collection plug-ins (but not the Teletronix LA-2A Legacy) use an internal upsampling technique. The upsampling results in a slightly larger latency than most other UAD plug-ins. See "Upsampled Plug-Ins" on page 563. for more information.

LA-2A Controls

Each model in the LA-2A plug-in collection has the same control set. The pa-
rameter descriptions below apply to all models unless otherwise noted.

Peak Reduction This control sets the amount of signal compression by adjusting the trigger threshold. Increasing the value lowers the threshold, and therefore increases the amount of compression. The available range is 0 dB (fully counter-clockwise) to -40 dB (fully clockwise).

Note: The front panel knob values, which range from 0-100, are arbitrary and do not reflect any particular dB value.

Rotate this control clockwise until the desired amount of compression is achieved. To monitor the amount of Peak Reduction, set the VU Meter knob to Gain Reduction. Peak Reduction should be adjusted independently of the Gain control.

When Peak Reduction is set to its minimum value, no compression (or limiting) occurs but the signal is still colored by the circuitry and the output level can be adjusted with the Gain control.

Gain The Gain knob increases the output level by up to 40 dB to compensate for the reduced level that results from compression. Adjust the Gain control after the desired amount of compression is achieved with the Peak Reduction control. The Gain control does not affect the amount of compression.

Note: The front panel knob values, which range from 0-100, are arbitrary and do not reflect any particular dB value.

- Meter Knob This rotary knob sets the mode of the VU Meter. When set to Gain Reduction, the VU Meter indicates the Gain Reduction level in dB. When set to +10 or +4, the VU Meter indicates the output level in dB (when set to +4, a meter reading of 0 corresponds to an output level of +4 dB).
- **VU Meter** This is a standard VU meter that displays either the amount of gain reduction, or output level, depending upon the setting of the Meter Function switch.

On/Power Switch Determines whether the plug-in is active. When the Power switch is in the Off position, the plug-in is disabled and UAD DSP usage is reduced (unless UAD–2 DSP LoadLock is enabled).

Compress/Limit This switch sets the compression ratio of the leveler. When set to Compress, the compression ratio is approximately 3:1 and when set to Limit, the ratio is approximately infinity:1. However, the compression ratios are nonlinear and frequency dependent, so these figures are not absolute.

Note: Like the original hardware, this control is unavailable on the Teletronix LA-2 plug-in. The plug-in is "hardwired" in Limit mode.

Emphasis The (R37) Emphasis "set screw" knob controls a shelf filter circuit in the compressor's sidechain input, thereby enabling frequency-dependent compression.

> When the control is fully clockwise (the default position), the sidechain signal is unfiltered and all frequencies in the source signal that exceed the compression threshold will trigger gain reduction equally (within the non-linear constraints of the electro-optical characteristics).

> Rotating the Emphasis control counter-clockwise increases filtering of the sidechain signal. The Emphasis filter gradually reduces the lower frequency content of the sidechain signal, resulting in compression that is less sensitive to those frequencies, and more sensitive to high frequency content. Therefore, as the sidechain filtering is increased, higher frequencies are compressed more.

Note: Emphasis is unavailable on the Teletronix LA-2A Legacy.

Side-Chain Pre-Emphasis (R37) Background

The LA-2A hardware was designed for use in broadcast applications. The audio signal in FM broadcasting undergoes pre-emphasis and results in a 17 dB boost at 15 kHz. Due to this increase in signal level, transmitters are subject to over-modulation. The LA-2A hardware provides a control (R37) which controls the amount of high-frequency compression.

This potentiometer is factory set for a "flat" side-chain response (clockwise). Increasing the resistance of this potentiometer by turning it counter-clockwise will result in compression which is increasingly more sensitive to the higher frequencies.

Historical Background

In the 1950s while at Parsons Electronics, Electrical Engineer Jim Lawrence was quietly asked to join the Titan Missile Program based at Cal Tech's Jet Propulsion Lab and was assigned to develop optical sensors for the program. Fortunately for everyone, the technology developed from Lawrence's work lead back to a more peaceful deployment of the optical sensor, as the detector in his future Leveling Amplifier. The interactions of the luminescent panel with the photo resistors in his T4 design are predominantly what gives the Teletronix Levelers their signature sound.

Lawrence later broke out on his own to start Teletronix, setting up shop in his hometown of Pasadena, California in 1958. Among the Teletronix line of products were transmitter tubes, multiplex generators, to full-scale radio transmitters. Jim's first pass at his Leveling Amplifier was realized as the Teletronix LA-1; Around 100 units were made. Lawrence then updated the design to the LA-2 with improved specs and circuit layout, then moved quickly to the industry standard LA-2A. In 1965, just three years after the incarnation of the LA-2A, Jim Lawrence sold the company to Babcock Electronics. Enter Bill Putnam. Putnam picked up Babcock's broadcast division including Teletronix, and rolled it into his parent company, Studio Electronics in 1967. From there, Universal Audio resumed manufacturing of the LA-2A, and Putnam began using the optical detector for new designs.

Whether serendipity or by intent, Jim Lawrence's Teletronix Levelers and his T4 design had the right musical response that allowed the LA-2A the sonic and technological longevity it still retains. Universal Audio spent a long time getting the T4 right for their hardware LA-2A reissue and the plug-in. But what was special about it wasn't fully understood until UA began the research to model the LA-2A for the UAD-1. Modern photocells are designed to be as fast as possible, but they don't have the right multi-stage response they need to sound like a Teletronix design. Our DSP research helped us understand how the original T4 worked at the quantum physics level. This not only allowed us to develop an accurate DSP model of the gain reduction behavior, it also helped us make our hardware T4 more consistent. This involved studying the original photocell formula, working with both modern device physicists and the people who developed the original photocells, locating the special equipment originally used to manufacture these back in the '60s, and re-qualifying the manufacturer. Whether hardware or DSP, it is this special qualified manufacturing process and "recipe" UA re-established that gives the LA-2A its unique, musical sonic quality to this day.

The Teletronix LA-2A Leveler Collection Original Hardware

CHAPTER 53

Thermionic Culture Vulture

Introduction

The original boutique, all-valve, studio distortion tool

A singular, enigmatic piece of all-valve boutique hardware, the Thermionic Culture Vulture is a distortion hedonist's malleable plaything. For more than 15 years, this British-made, studio-grade, high-gain valve unit has provided a palette of vivid distortion colors — from sublime thickening textures to demonic growls of perverted mayhem — on countless genre-spanning recordings.

Now — thanks to an intense multi-year engineering effort from Universal Audio — you can track and mix with the only authentic circuit emulation of this one-of-a-kind valve distortion tool with the Thermionic Culture Vulture plug-in.

Dominate your Sources with Three Valve Topologies

The Culture Vulture plug-in perfectly emulates all of the original hardware's sonic proclivities and diabolical details, including the rich harmonic content of its three distinct all-valve circuit topologies. With its full palette of high-gain, studio-grade, dual-stage valve distortion, you can subtly color or utterly destroy existing tracks, buses, or a full mix.

Triode mode can gently warm any source, from a mix bus to a DI bass or synth signal tracking real time through an Apollo interface. Or add more oddorder harmonic edginess to a vocal or rhythm guitar with Pentode 1. Not enough pain? Tap into the nearly-impossible-to model Pentode 2 mode — a unique, mad-genius circuit that inspires creativity and invites experimentation with it's opulent range of demented distortions.

Authentic, All-Valve Circuit

The Thermionic Culture Vulture perfectly captures the natural, "in-between-the transients" dynamic bias response inherent in the Culture Vulture's valvedriven circuit — as well as its powerful stereo control set. The Drive knobs and Overdrive switches control the amount of input signal hitting the 6AS6 valves — with up to 20 dB of gain from Overdrive alone! The Bias controls adjust the incoming voltage, providing dramatic differences in response, from clean to distorted, voltage-starved chatter, and gating effects. The Filter controls (9 kHz and 6 kHz) can be used to fine-tune your distortion flavors even further.

While the Thermionic Culture Vulture is not a compressor per se, it can act as sonic "glue" on a bus or an entire mix, deftly teasing out tantalizing sizzle and detail with authentic valve heat.

Thermionic Culture Vulture Screenshot

Figure 162. The Thermionic Culture Vulture plug-in window

Operational Overview

Two Channel Processor	Thermionic Culture Vulture is a two-channel device capable of running in ste- reo or dual-mono modes. When used on a stereo signal, the active mode is determined by the Control Link switch. When the plug-in is used in a mono- in/mono-out configuration, the controls for either channels can be used to ad- just settings.
Controls Layout	Like the original hardware, the arrangement of the controls for Channels 1 and 2 have a mirror image of each other (the Channel 2 controls have re- versed ordering compared to the Channel 1 controls).
	Note: Parameter ordering is not mirrored in Controls mode (available in some DAWs) or automation views.
Unorthodox Controls	Some plug-in controls (Bias, Filter, Bypass, Power) are "backwards" when compared to traditional hardware designs. These anomalies are true to the original hardware design.

Expanded
Feature SetThe Culture Vulture plug-in offers two key features not found on the original
hardware: Mix and Control Link.

The Mix control can be used for parallel processing on any bus, adding gentle valve presence, punch, and grit to drums, vocals, or an entire mix. With the Control Link function, perfectly matched stereo imaging is possible to save time and preserve balances.

Artist Presets The Thermionic Culture Vulture plug-in includes artist presets from prominent users. The artist presets are in the internal factory bank and are accessed via the host application's preset menu. The artist presets are also placed by the UAD installer so they can be used within Apollo's Console application. The presets can be loaded using the Settings menu in the UAD Toolbar (see "Using UAD Powered Plug-Ins" in Chapter 7 of the UAD System Manual).

This plug-in includes additional artist presets that are not available in the internal factory bank. These additional presets can also be accessed using the Settings menu in the UAD Toolbar.

Upsampled
Plug-InThis plug-in uses an internal upsampling technique to achieve sonic design
goals. The upsampling results in a slightly larger latency than other UAD plug-
ins (55 samples; 88 samples at 176.4 and 192 kHz).

This additional latency is automatically compensated by modern digital audio workstations and is essentially undetectable. See "Upsampled Plug-Ins" on page 563 for more information.

Thermionic Culture Vulture Controls

Controls for Channel 1 and Channel 2 are identical and therefore are only described once. The Link, Mix, and Power controls apply to both channels.

Drive

Drive adjusts the amount of input gain (amplified by the EF86 input stage valve), that is sent to the 6AS6 distortion valve. Rotating this control clockwise increases the amount of distortion.

The available Drive range is from 1 to 11. The values are arbitrary and do not represent absolute levels.

Bias Bias varies the amount of current passed through the cathode in the 6AS6 distortion valve. The amount of Bias current is displayed by the Meters.

Bias has a significant impact on the distortion characteristics. True to the original hardware, the behavior of this control is reversed.

Clockwise (forward) rotation *decreases* bias current and generally produces a cleaner and thinner sound. At lower bias currents, the cathode is "starved" and the signal collapses more easily. At the lowest settings, only signal peaks are passed through the valve, resulting in a gating effect.

Counter-clockwise (backward) rotation *increases* bias current and generally produces a thicker, rounder tone with more harmonic distortion. At higher bias currents, the cathode is "over-fed" and outputs rich, fat distortion.

Medium settings are generally best for gently warming sounds without obvious distortion. The cleanest setting is at approximately 0.25 to 0.3 milliamperes.

The default Bias knob value is 6 for 0.45 milliamperes of bias current. The knob values of 1 to 11 are arbitrary and do not represent absolute levels.

Distortion Type

The 6AS6 distortion valve can operate in three different operating modes by changing the internal wiring of the tube circuit. Distortion Type switches this mode so different characteristics can be obtained. This switch interacts extensively with the Drive, Bias, and Overdrive controls. The available distortion types, and their characteristics, are described below.

T (Triode)

Triode mode generates more 2nd-order (even) harmonics and is generally the cleanest, smoothest, and "sweetest" mode. Triode mode is great for adding tube warmth to signals without obvious distortion.

P1 (Pentode 1)

Pentode 1 mode generates more 3rd-order (odd) harmonics and has a harder, edgier, and louder sound than Triode mode.

P2 (Pentode 2)

Pentode 2 mode has an unusual wiring for a pentode circuit and a particularly aggressive sound, especially with high Bias current and/or when Overdrive is engaged.

This setting can produce some of the most unusual and over-the-top effects such as frequency doubling, gating, and stuttering. It is normal for this mode to be quieter than Triode or Pentode 1 modes.

Interesting phase behaviors can also be induced in this mode. Depending on the source signal, polarity may invert at extreme settings.

Overdrive Overdrive applies 20 dB of additional gain to the 6AS6 distortion valve input for increased distortion.

Note: Exercise caution when engaging Overdrive, as output levels can increase significantly (depending on other control settings).

Overdrive is engaged when the switch is in the *down* position. The default value is off (up position). Like the Filter, Bypass, and Power switches, the behavior of this control is reversed from typical hardware designs.

The behavior of this switch has a variation from the original hardware. When Overdrive is off (up position), 9 dB of clean gain is added to the input signal. The extra gain is included in the plug-in to compensate for the extreme level changes that occur in the original hardware when Overdrive is engaged (making it easier to quickly compare signals with Overdrive off and on), and also to provide for a more usable range of clean settings.

Filter	FILTER Filter applies a 12 dB per octave high pass filter at the output of the 6AS6 distortion valve circuit for a smoother sound.
	Like the Overdrive, Bypass, and Power switches, the behavior of this control is reversed from typical hardware designs. Filter is engaged when the switch is in the two <i>down</i> positions. The default value is off (up position).
	Note: There is a slight rolloff of upper frequencies even when Filter is set to Off. However, this rolloff does not occur when Distortion Type is set to P2.
Output Level	Output Level controls the amount of signal going into the output valve (type 5963), which has its own coloration.
	Knob values of 8–9 produce the cleanest output. Set- tings above 9 will overdrive the output valve for increased distortion.
	The available range is from 1 to 11 and the default value is maximum. The values are arbitrary and do not represent absolute levels.
Bypass	Bypass disables plug-in processing. If a full bypass is desired to con- serve UAD DSP, use the Power switch.
	Distortion processing is enabled when the switch is in the <i>down</i> po- sition. Like the Filter, Bypass, and Power switches, the behavior of this control is reversed from typical hardware designs.
Control Link	This switch causes the controls for Channels 1 and 2 to be stereo linked. When engaged (right position), adjusting a control on one channel will cause the equivalent control on the other channel to move to the same value.
	When the plug-in is used in a stereo (or mono-in/stereo-out) configuration, Control Link is engaged by default. Disable the control (left position) for inde- pendent dual-mono processing on stereo signals.
	When used in a mono configuration, the switch is fixed in the linked position.
	<i>Important:</i> When Control Link is engaged, all Channel 1 values are copied to Channel 2, and any control offsets between channels are lost.

Mix

The output balance between the signal processed by the plug-in and the original dry source signal can be adjusted with the Mix control. Mix facilitates parallel processing techniques without having to create additional routings in the DAW.

When set to 0% (minimum), only the unprocessed (dry) source signal is output. When set to 100% (the default value), only the processed (wet) signal is output. When set to 50%, an equal blend of both the dry and wet signals is output. The balance is continuously variable and phase accurate throughout the control range.

Power This switch determines whether the plug-in is active. When the Power switch is in the Off (up) position, plug-in processing is disabled and UAD DSP usage is reduced (unless UAD-2 DSP Load-Lock is enabled).

Like the Filter, Overdrive, and Bypass switches, the behavior of this control is reversed from typical hardware designs.

Power Lamp

The lamp above the Power switch is illuminated when the plug-in is active.

Tip: Click the Power Lamp to toggle the enable/disable state of the plug-in.

Meters

being adjusted).

The meters display the bias current, in milliamperes, flowing through the 6AS6 distortion valve. Bias current can be adjusted with the Bias control.

Note that the bias current can be affected by the source material, especially at very high distortion settings. Additionally, depending on input signal levels, the Meters may fluctuate when Bias is not

"Warning: Do not take this unit seriously. The Culture Vulture is a fun effects unit and has been designed for maximum pleasure!"

The Thermionic Culture Vulture Hardware Unit

CHAPTER 54 Trident A-Range EQ

Overview

The original Trident A-Range desk holds near-mythic status in the professional recording industry, and is arguably the best loved of the classic Trident console designs. Particularly noted for its fantastic preamps and the unique band interactions of its colorful EQ section, the Malcolm Toft / Trident-designed A-Range console has made an indelible impact on the sound of record making. During the "Golden Years" of rock, the A-Range was employed to record some truly great records — David Bowie's The Rise and Fall of Ziggy Stardust, Lou Reed's Transformer and Queen's Sheer Heart Attack, to name a few — helping to solidify this console's reputation forever. And now, this sound comes to the UAD Powered Plug-Ins platform, courtesy of the Trident A-Range Classic Console EQ plug-in.

Working in partnership with Trident Audio Developments, UA scrupulously analyzed and faithfully reproduced the EQ section from the specific Trident A-Range console used to record classic albums by both The Police and Rush. One of only 13 A-Range consoles ever built, this desk was hand-picked by Elliott Smith for his private studio, and now resides at New Monkey Studio in Van Nuys, CA.

Trident A-Range EQ Screenshot

Figure 163. The Trident A-Range EQ plug-in window

Operational Overview

Unique Band Interactions & Distinct Cut-Filter Combinations

The unique inductor-based EQ section of the board is what the Trident A-Range sound is all about. A series of three high pass filters and three low pass filters are arranged at the ends of the EQ section (see Figure 164). These are unique in that the switches can be pushed in simultaneously, offering distinct cut filter combinations with unusual filter curves.

The rest of the EQ section contains four bands: low shelf, low-mid bell, high-mid bell, and high shelf (see Figure 164). Each band has four selectable fixed frequencies and ± 15 dB of gain. These were the good old days before sweepable frequencies and bandwidth controls, but the results are wonderfully warm and musical. The controls complement is rounded out with phase, output level, and bypass.

There is band interaction between the high and low shelving filters, and also between the low-mid and high-mid bell filters. The midband interactions can be significant if the center frequencies are near each other.

Band Layout Each of the four main EQ bands have similar controls. The band frequency is controlled by its knob, and the band gain is controlled by its slider.

Figure 164. Trident A-Range band control layout

Trident A-Range EQ Controls

The Phase (Ø) button inverts the polarity of the signal. The signal is inverted when the button is engaged (darker). Leave the button inactive (lighter) for normal phase. Phase is independent of the EQ IN setting.

Low Pass Filters Three low pass filters are available, and they can be used simultaneously in any combination. The available cutoff frequencies are 15 kHz, 12 kHz, and 9 kHz with a slope of 12 dB per octave. Each filter is active when its button is engaged (darker).

Each low pass filter "adds" to the others. For example, engaging the 15K filter will rolloff frequencies above 15 kHz, but engaging 9K as well will also attenuate frequencies above 15 kHz, even more than if 15K was used by itself.

Note: See Figure 164 on page 534 and Figure 165 on page 536 when referring to the band parameters below.

High Shelf The high shelf offers Trident-A's famous high frequency shelving EQ.

High Shelving Frequency

The edge frequency of the high shelf filter is specified by this knob. Four shelf edge frequencies are available: 15 kHz, 12 kHz, 10 kHz, and 8 kHz.

High Shelving Gain

The gain for the high shelf filter is specified by the horizontal slider control. The available range is ± 15 dB. The gain value is zero when the slider is in the center position.

High-Mid Band The high-mid EQ offers peak/dip "bell" equalization for the high-to-middle frequencies.

High-Mid Frequency

The center frequency of the high-mid filter is specified by this knob. Four center frequencies are available: 9 kHz, 7 kHz, 5 kHz, and 3 kHz.

High-Mid Gain

The gain for the high-mid filter is specified by the horizontal slider control. The available range is approximately ± 15 dB. The gain value is zero when the slider is in the center position.

Low-Mid Band	The low-mid EQ offers peak/dip "bell" equalization for the middle-to- low fre- quencies.
	Low-Mid Frequency
	The center frequency of the low-mid filter is specified by this knob. Four center frequencies are available: 2 kHz, 1 kHz, 500 Hz, and 250 Hz.
	Low-Mid Gain
	The gain for the low-mid filter is specified by the horizontal slider control. The available range is approximately ± 15 dB. The gain value is zero when the slider is in the center position.
Low Shelf	The low shelf offers low frequency shelving equalization.
	Low Shelving Frequency
	The edge frequency of the low shelf filter is specified by this knob. Four shelf edge frequencies are available: 150 Hz, 100 Hz, 80 Hz, and 50 Hz.
	Low Shelving Gain
	The gain for the low shelf filter is specified by the horizontal slider control. The available range is ± 15 dB. The gain value is zero when the slider is in the center position.
Gain slider shortcuts	The band gain sliders can be instantly moved to any position by clicking any- where within its range.
	Tip: Clicking just above or below the "0" (zero) graphic returns the associated slider to its center (zero gain) position.

Figure 165. Trident A-Range slider shortcuts

The band gain sliders will jump to any position clicked within the red zones.

Click near the "0" to return to zero gain.

High Pass Filters Three high pass filters are available, and they can be used simultaneously in any combination. The available cutoff frequencies are 100 Hz, 50 Hz, and 25 Hz with a slope of 18 dB per octave. Each filter is active when its button is engaged (darker).

> Each high pass filter "adds" to the others. For example, engaging the 50 Hz filter will rolloff frequencies below 50 Hz, but engaging 100 Hz as well will also attenuate frequencies below 50 Hz, even more than if 50 Hz was used by itself.

Output Level

The Output knob controls the signal level that is output from the plug-in. The default value is 0 dB. The available range is –24 dB to 12 dB.

Tip: Click "Output' or "0" (zero) to return to zero gain position.

EQ In The EQ In switch determines whether the plug-in is active. When the switch is in the Off (lighter) position, plug-in processing is disabled and UAD DSP usage is reduced (unless *UAD-2 DSP LoadLock* is enabled). Note the Phase setting ("Phase" on page 535) remains in effect even if EQ In is in the off position.

Trident A-Range Latency

The Trident A-Range EQ uses an internal upsampling technique. This upsampling results in a slightly larger latency than other UAD plug-ins. See "Upsampled Plug-Ins" on page 563 for more information.

Note: Compensating for Trident A-Range EQ is not required if the host application supports full plug-in delay compensation throughout the signal path, or when it is used only on the outputs.

CHAPTER 55

UA 1176 Classic Limiter Collection

History

The Definitive Collection of the World's Most Famous Compressors

The original Universal Audio 1176, designed by audio Renaissance man and UA founder M.T. "Bill" Putnam, represented a major breakthrough in limiter technology. The first true peak limiter to feature all-transistor circuitry and FET gain reduction, the original 1176 offered superior performance and a signature sound — including a lightning-fast 20 microseconds attack time. Ever since its announcement in 1967, the 1176 has lent its character and punch to some of the greatest recordings in history — creating a solid framework for any mix, in any genre.

Evolved from the popular Universal Audio 175 and 176 tube limiters, the 1176 retained proven qualities of these industry leaders, and set the standard for all limiters to follow. Entries found in Putnam's design notebook point to his extensive experimentation with the newly developed FET (Field Effect Transistor) in various configurations. Eventually, he found a way of using the FET as the gain-controlling element of a compressor/limiter. While the 1176 has seen a huge number of revisions in its history, the most significant revision was by UREI engineer, Brad Plunkett, in an effort to reduce noise — hence the birth of the 1176LN at Rev C. Numerous design changes have followed since, resulting in at least 13 revisions and variations of the 1176.

Universal Audio released its first 1176 plug-in emulation, the UAD 1176LN, in 2001. This plug-in launched the UAD platform, and inspired a decade of analog emulation software.

Today, with the Universal Audio 1176 Limiter Plug-Ins Collection, we've circled back to the 1176 and modeled its entire electronic path from stem to stern — including its transformers, FET and bipolar transistor amplifiers, with improvements in its gain reduction nonlinearities and Attack/Release fits. The resulting 1176 Classic Limiter Plug-In Collection provides unrivaled emulations of three distinct 1176 units, and is indispensable for any serious engineer or producer.

UA 1176 Screenshots

Figure 168. The UA 1176AE plug-in window

Figure 169. The UA 1176LN Legacy plug-in window

Figure 170. The UA 1176SE Legacy plug-in window
1176 Plug-In Family

The complete 1176 family is comprised of five individual plug-ins, as seen on the previous page. Each variation has its own unique sonic characteristics.

UA 1176 Limiter Collection The UA 1176 Limiter Collection bundle (introduced in UAD v6.2) provides three distinct 1176 revisions, representing over 40 years of design iterations to the original 1176 — the world's most recognized compressor.

The newer state-of-the-art algorithms in this bundle take full advantage of the extra power available on UAD-2 devices and the design sophistication and expertise gained since the introduction of the legacy 1176LN plug-in ten years prior.

1176 Rev A "Bluestripe"

This model (Figure 166 on page 540) represents the original Putnam FET limiter design, complete with its higher distortion and unique FET gain amplifier characteristics.

Although the input can clip even when gain reduction is not occurring in all the Limiter Collection bundle models, the input clipping is most evident on the Rev A model.

1176 Rev E "Blackface"

This model (Figure 167 on page 540) covers the early 70's / Brad Plunkett "LN" (Low Noise) era of the 1176 circuit lineage, with variations including a more linear compression response, transistor gain amplification, and a change to the program dependency.

1176AE "Anniversary Edition"

This model (Figure 168 on page 540) provides UA's rare 1176 40th Anniversary Edition, complete with exclusive "hot-rod" mods — including its lower 2:1 compression ratio and a fixed "super slow" 10 ms attack mode.

UA 1176LN/SE The 1176 legacy bundle includes the UA 1176LN Legacy and UA 1176SE Legacy plug-ins. These first-generation plug-ins run on UAD-1 and UAD-2 devices.

To accommodate the limited DSP resources of the UAD-1, the input transformer and I/O distortion characteristics were not modeled in these plug-ins. This makes the legacy LN/SE versions especially useful in situations where less distortion is desirable.

UA 1176LN Legacy

The UA 1176LN Legacy plug-in (Figure 169 on page 540) was, along with the LA-2A, the first plug-in available for the UAD platform. It still has a great sound and is very usable, especially when there are not enough DSP resources to use the second-generation versions in the newer UA 1176 Limiter Collection.

UA 1176LN SE Legacy

The UA 1176SE Legacy "Special Edition" (Figure 170 on page 540) is derived from the UA 1176LN Legacy plug-in. Its algorithm was revised in order to provide sonic characteristics similar to the UA 1176LN Legacy, but with significantly less DSP usage. It provides "1176LN-like sound" when DSP resources are particularly constrained. The UA 1176SE Legacy sound and behavior is practically identical to the UA 1176LN Legacy at nominal settings; at extreme (cranked) settings, the differences are more obvious.

Operational Overview

Applications	Generally speaking, the primary use for the 1176 plug-ins are as individual inserts for sources that require compression, such as an individual snare, vo- cal, or guitar track, or for multi-instrument sources such as a stereo drum buss.
	Because the UA 1176 Limiter Collection also models the input and output am- plifiers, these models can also be used as "tone boxes" to add 1176 color without compression/limiting by disengaging the ratio control (all Ratio but- tons "up").
Parameters	Using an 1176 is a study in simplicity. Input simultaneously sets compression threshold and the level of the signal entering the 1176; Output sets the final signal level. Attack sets the time it takes the 1176 to respond to incoming signal, while Release sets the time it takes the 1176 to return to its initial level. The VU meter displays the amount of gain reduction (GR) or output level $(+4/+8)$.
	The four Ratio buttons determine the degree of compression; lower ratios for compression, higher ratios for limiting. Disengaging all the Ratio buttons (Shift+Click the currently selected ratio) disables compression altogether, but signal continues to pass through the 1176 circuitry. This is commonly used to add the "color" of the 1176LN without any gain reduction. At the request of users, the wide range of "Multi-Button" combinations possible with the hardware is now possible — including the famous "All Button" sound.
Control Response & Interactions	The UA 1176 Limiter Collection plug-ins are meticulous emulations of the orig- inal hardware in every regard, including control responses and interactions. Each 1176 has unique characteristics for gain, threshold, compression knee, distortion onset, and sweet spots. Setting the controls to the same positions on the different plug-ins may yield radically different results, especially depend- ing on the source signals.
	This accurate control modeling also applies to the Input and Output control tapers and amplifier levels. The same knob positions on one 1176 could pro- duce a dramatically louder (or softer) levels on another. For this reason (to prevent unexpected and potentially damaging output level jumps), presets are not interchangeable between the 1176 variations.

Grit	A simple 1176 trick is turning the attack and release up all the way to their fastest setting. This has the audible effect of adding compression distortion to the audio source, and is especially pronounced in all-buttons mode. What happens here is the attack and release are happening so fast that minute level fluctuations sound like distortion. It can add a very useful, gritty compression effect.
	This effect is useful on bass, where you might need compression and distortion at the same time, and the 1176 can provide both in a unique way. This trick also sounds great on screaming lead vocals.
Artist Presets	The UA 1176 Limiter Collection includes artist presets from prominent 1176 users. Some of the artist presets are in the internal factory bank and are accessed via the host application's preset menu. Additional artist presets are copied to disk by the UAD installer. The additional presets can be loaded using the Settings menu in the UAD Toolbar (see "Using UAD Powered Plug-Ins" in Chapter 7 of the UAD System Manual).
	Note: Presets created with the original 1176LN Legacy and 1176SE Legacy plug-ins are incompatible with the newer Classic Limiter Collection plug-ins.
Upsampling	The UA 1176 Classic Limiter Collection plug-ins (but not the UA 1176LN Leg- acy or UA 1176SE Legacy) use an internal upsampling technique. The up- sampling results in a slightly larger latency than most other UAD plug-ins. See "Upsampled Plug-Ins" on page 563 for more information

1176 Controls

	Each 1176 plug-in variation has the same control set, so they are only de- tailed once. The parameter descriptions below apply to all models unless oth- erwise noted.
Input	Input adjusts the amount of gain reduction as well as the relative threshold. Rotate the knob clockwise to increase the compression amount.
	Like the original hardware, the label values are somewhat arbitrary; the knobs are not calibrated to any particular dB values and levels will vary be- tween the various plug-in models. Even when the Input knob is set to "∞" sig- nals can still pass into the processor and be compressed.
	Note: In the UA 1176 Limiter Collection plug-ins, increasing Input will increase distortion.
Output	Output determines the final output level of signal leaving the 1176. Once the desired amount of limiting or compression is achieved with the use of the Input control, the Output control can be used to make up any gain lost due to gain reduction.
	To monitor the Output level, set the VU Meter to +8 or +4. The Output control does not affect the amount of compression.
	Note: In the 1176 Limiter Collection plug-ins, increasing Output will increase distortion.
Attack	Attack sets the amount of time it takes the 1176 to respond to an incoming sig- nal and begin gain reduction. The 1176 attack time is adjustable from 20 microseconds to 800 microseconds (both extremely fast).
	The attack time is fastest when the Attack knob is in its fully clockwise position, and is slowest when it is in its fully counter-clockwise position. When a fast at- tack time is selected, gain reduction kicks in almost immediately and catches transient signals of very brief duration, reducing their level and thus "soften- ing" the sound.
	Slower attack times allow transients (or partial transients) to pass before lim- iting or compression begins on the rest of the signal. Note that the actual at- tack time varies slightly based on the selected ratio and the particular plug-in model in use. Lower ratios will maintain the fastest attack times.

The behavior of the Attack knob varies slightly between the models, as detailed below.

UA 1176AE Attack

The 1176AE offers a unique, fixed 10 ms "SLO" Attack mode when this control is moved to the fully counter-clockwise position.

UA 1176 Rev A and UA 1176LN Rev E Attack

When Attack is in the OFF position the I/O amplifiers remain active while the compression circuit is bypassed. This enables these models to add 1176 color without dynamics processing. This function is identical to disengaging all the Ratio buttons.

Note: To avoid unexpected level changes that can result when compression is disengaged, on these models the OFF text label must be clicked to move the Attack knob to the OFF position.

UA 1176LN/SE Legacy Attack

The OFF position is unavailable in these plug-ins. To bypass plug-in processing in these models, use the Meter OFF button.

Release Release sets the amount of time it takes the 1176 to return to its initial (pregain reduction) level. The 1176 release time is adjustable from 50 milliseconds to 1100 milliseconds (1.1 seconds).

> Note that the actual release time varies slightly based on the particular plugin model in use and also partially depends on the program material.

> The release time is fastest when the Release knob is in its fully clockwise position, and is slowest when it is in its fully counter-clockwise position. If the release time is fast, "pumping" and "breathing" artifacts can occur, due to the rapid rise of background noise as the gain is restored. If the release time is too slow, however, a loud section of the program may cause gain reduction that persists through a soft section, making the soft section difficult to hear.

About Program-Dependent Release

	Program-dependent release is a feature of many compressors. The motivation for having program-dependent release is as follows: After a transient, it is de- sirable to have a fast release to avoid prolonged dropouts. However, while in a continued state of heavy compression, it is better to have a longer release time to reduce the pumping and harmonic distortion caused by repetitive at- tack- release cycles.
	The 1176 compressor employs a release mechanism that is heavily program- dependent. There are three features to a program-dependent release: A fast release-time, a slow release-time, and a transition-time.
	The fast release time is the effective release time after transients; the slow re- lease time is the release time after sustained high-RMS signals. The transition time expresses how long the signal must be "in compression" before the slow release time comes into effect.
	The original "Bluestripe" and 1176AE has a different slow release-time and transition-time when compared to the "Blackface" revisions.
Ratio	The four Ratio pushbutton switches (to the left of the VU Meter) determine the compression ratio of the plug-in. Ratios of 20:1, 12:1, 8:1, and 4:1 are available for all 1176 models except the UA 1176AE, which has 20:1, 8:1, 4:1, and 2:1 modes.
	The 20:1 ratio is typically used when peak-limiting is desired, while the lower ratios are typically used for general dynamic range compression.
Multiple Ratio Buttons	One of the most unique features of the 1176 hardware is the ability to press multiple Ratio buttons in simultaneously to create unusual compression or lim- iting behavior and increased compression distortion. See Figure 171 on page 548 for available modes.
All Button Mode	Engineers typically use "All Button" mode on drums or on ambience or room mics. It can also be used to make a bass or guitar sound "dirty" or for putting vocals "in your face." In All-Button mode (sometimes also known as "British Mode"), distortion increases radically due to a lag time on the attack of initial transients.

	In All Button mode the ratio goes to somewhere between 12:1 and 20:1, and the bias points change all over the circuit, thus changing the attack and re- lease times as well. The unique and constantly shifting compression curve that results yields a trademark overdriven tone that can only be found in this family of limiter/compressors.
	All Button mode is available in all 1176 models.
Multi Button Modes	The UA 1176 Limiter Collection includes the ability to select a variety of "Multi Button" combinations, offering various interpretations of the "All Button" idio- syncrasies. Various button combinations will yield audibly different compres- sion characteristics.
Selecting All/Multi Button Ratio Modes	 In UA 1176 Limiter Collection To select the various combinations of multiple buttons, shift+click the Ratio buttons. Combinations are limited to the modes that actually affect the sound in the hardware. See Figure 171 below for the available combinations. For the combinations with three or more buttons, the shift-clicking the outer buttons will automatically engage the inner buttons (the inner buttons cannot be disengaged; such combinations don't affect the sound in the hardware). These models can be used as "tone boxes" without compression/limiting by disengaging the Ratio control altogether (all Ratio buttons "up"). This is accomplished by clicking any Ratio button so only one button is engaged, then shift-clicking the engaged button so none are engaged.

In UA 1176LN/SE Legacy

• To select All Button mode on the UA 1176LN/SE Legacy, shift+click any Ratio button.

Available Multi Button Modes

Figure 171. The Multi-Button modes available in the UA 1176 Limiter Collection. All-Button mode (far right) is available in 1176LN and 1176SE.

VU Meter This is a standard VU meter that displays either the amount of gain reduction, or output level, depending upon the setting of the Meter Function switch.

Meter Function These four pushbutton switches (to the right of the VU Meter) determine the mode of the VU Meter, and whether the plug-in is enabled. When set to GR, the VU Meter indicates the Gain Reduction level in dB. When set to +8 or +4, the VU Meter indicates the output level in dB; when set to +4, a meter reading of 0 corresponds to an output level of +4 dB.

When the Meter Function is set to GR mode and multiple Ratio buttons are engaged, the Meter will appear to behave strangely. This is normal behavior in the 1176 hardware, and is faithfully recreated in the plug-in.

When the OFF switch is engaged, the plug-in is disabled and UAD DSP usage is reduced (unless UAD-2 LoadLock is enabled).

The UA 1176 Limiter Collection Original Hardware

CHAPTER 56

UA 610 Tube Preamp & EQ Collection

Historical to Modern Tube Amplification from Universal Audio

The Universal Audio 610-A Modular Amplifier was designed by audio renaissance man and UA founder M.T. "Bill" Putnam, and set a major milestone in console design. An all tube and transformer class-A design with feedback style EQ, the 610-A was the first preamp design to include echo sends and modularity which allowed channels to be swapped mid-recording session.

The 610-B is the current Universal Audio design employed in the popular modern equivalents such as the Universal Audio 2-610 and 6176. The sheer number of classic recordings made by the 610, new or old, is staggering. From Coldplay to Cold War Kids, and Duke Ellington to The Doors, the 610 has been part of the fabric of modern recording since 1958.

With over a year in research and design, the UA 610 Preamp and EQ Collection represents the next major milestone in the evolution of Universal Audio's 610, and for preamplification as a whole. For the first time, the UA 610 Preamplifier and EQ Collection plug-ins offer the complete sound, behavior and features of a dedicated tube preamp.

UA 610 Screenshots

The UA 610 Plug-Ins

	The UA 610 Tube Preamp Collection is comprised of two distinct plug-ins, as shown in Figure 172 on page 551: The vintage UA 610-A, and the modern UA 610-B. Each plug-in has its own modeling and each captures its unique segment in the 610's sonic history.
	The complete signal path is modeled for both 610 plug-ins, including tube am- plifiers and transformer components, along with all the phase shift and distor- tion characteristics that are inherent in each hardware preamp.
Vintage 610-A	The original 610 Modular Amplifier had two versions; the 610 and the 610-A. Besides minor cosmetic differences (such as updates to the panel lay- out and the UA logo), the only circuit difference between the two was the ad- dition of a +3 dB setting to the 10 kHz High Shelf EQ.
	The UA 610-A plug-in models the vintage 610-A module in the original Wally Heider "Green Board" console.
Modern 610-B	The 610-B is the modern Universal Audio preamp design used in our popular hardware products such as the 2-610, LA-610mkII, and 6176.
	The UA 610-B plug-in is modeled from the Universal Audio 2-610 Dual Chan- nel Tube Preamplifier hardware, including all the expanded features opti- mized for modern use.
In Use	A primary use for either 610 plug-in is for individual vocal or instrument tracks where colorful tube character and broad EQ strokes are desired. The 610 is widely used as a vocal, bass, horn or strings channel by many modern users, but it sounds great on any source signals, as proven by over five decades of record making.
Tonal Range	From clean to clipped, with a broad sweet spot between, extreme tonal flex- ibility is possible with the 610-A and 610-B. The input and output circuits each have their own tube-driven gain stage, and because each stage imparts its own color, many variations can be obtained by tuning the I/O gain struc- tures. The UA 610 equalizers can also add lots of flavor. Because the EQ has a feedback-style design, it effects the distortion characteristics of the output stage.

Control Differences	The UA 610-A and UA 610-B plug-ins (Figure 172 on page 551) have simi- lar controls and layouts.
	For some parameters, the function of these controls is identical for both plug- ins. In the parameter descriptions below, controls and/or descriptions that are common to both plug-ins are detailed at the top of each control name sec- tion.
	Any differences and/or controls that are unique to each specific plug-in are detailed after the common description.
Presets	The UA 610 plug-ins include presets in the internal factory bank which are ac- cessed via the host application's preset menu. The presets are also copied to disk by the UAD installer so they can be used within Apollo's Console appli- cation. The presets can be loaded using the Settings menu in the UAD Toolbar (see "Using UAD Powered Plug-Ins" in Chapter 7 of the UAD System Manual).
UA 610 Latency	The UA 610 plug-ins use an internal upsampling technique to achieve sonic design goals. This upsampling results in a slightly larger latency (55 samples; 85 samples at 176.4 and 192 kHz) than non-upsampled UAD plug-ins. These additional samples are automatically compensated by modern host DAWs. See "Upsampled Plug-Ins" on page 563 for more information.
Unison™ Integration	The UA 610 plug-ins feature Unison mic preamp technology integra- tion with the mic preamp hardware in Universal Audio's Apollo au- dio interfaces. With Unison, Apollo's ultra-transparent mic preamps inherit all of the unique sonics, input characteristics, and features of the 610 hardware preamps, including the mic, line, and Hi-Z inputs.

Note: Unison is active only when the plug-ins are inserted in the unique IN-PUT insert within Apollo's Console application. For complete Unison details, see the Apollo Software Manual.

Realistic Tandem Control

Unison facilitates seamless interactive control of 610 preamp plug-in settings using Apollo's digitally-controlled panel hardware and/or the plug-in interface. All equivalent preamp controls (gain, pad, polarity, etc.) are mirrored and bi-directional. The preamp controls respond to adjustments with precisely the same interplay behavior as the 610 hardware, including gain levels and clipping points.

Hardware Input Impedance

All Apollo mic preamps feature input impedance switching in analog hardware that can be physically switched by Unison plug-ins for physical, microphone-to-preamp resistive interaction. This impedance switching enables Apollo's preamps to physically match the emulated unit's input impedance, which can significantly impact the sound of a microphone. Because the electrical loading occurs on input, prior to A/D conversion, the realism is faithful to the original target hardware preamp.

Tactile Gain Staging

Apollo's front panel preamp knob can independently adjust all gain and level parameters available within the Unison plug-in via Gain Stage Mode. The gain stage being adjusted can be remotely switched via Apollo, so multiple gain levels and their associated colorations can be tuned from the hardware knob for precise physical tactile control, all without using the Unison plug-in's software interface.

Input Level Controls

Input levels for the UA 610 plug-ins are controlled by the overall combination of the input select, pad, and gain controls available within each plug-in.

These parameters, which vary per model, control the first tube gain stage in the plug-ins. Generally speaking, higher input gains will produce more color in the signal.

Input Select The 610 hardware has both mic and line level inputs. The Input Select control switches between the "virtual input jacks" in the emulated models.

In most mic preamplifiers (including the 610), the difference between the mic and line inputs is simply that the line input is attenuated before entering the preamp circuitry. The gain circuits are not different for the mic and line inputs.

Line

When set to Line, it's as if the DAW signal is plugged into the line level input of the emulated 610 hardware. Less tube gain is applied, and a cleaner sound is obtained.

Mic

When set to Mic (with UA 610-B, the 500 and 2.0K settings), it's as if the DAW signal is plugged into the microphone input of the emulated 610 hardware and approximately 30 dB of additional (unattenuated) tube gain is applied. Since the incoming signal in from the DAW is already at line level, this mode will more readily result in the tube color, saturation, and/or clipping associated with overdriving the input.

Important: Use caution when switching to Mic from Line, as signal output levels can increase significantly (as they would with a hardware preamp).

UA 610-A

Mic and Line inputs are available. The mic input impedance of the 610-A hardware is 600Ω .

UA 610-B

Mic and Line inputs are available, with the additional availability of input impedance selections for the Mic input. The Mic input can be switched to 500Ω or $2K\Omega$; the different input impedances have subtle effects on the signal color and response.

Unison Impedance

When UA 610-A or UA 610-B is used in an INPUT insert within the Apollo Console application, the hardware input impedance of the Apollo mic preamp is switched to match the value in the plug-in for physical, microphone-to-preamp resistive interaction.

With UA 610-B, matching the microphone to the closest impedance value is generally recommended, but this parameter can be used creatively and will not harm equipment connected to the Apollo mic preamp.

Note: For complete Unison details, see the Apollo Software Manual.

Input Pad/Gain In addition to the Input Select switch, both plug-in models have Pad and Gain parameters that control the signal level at the tube input stage.

The Pad controls are used to attenuate incoming signals for less coloration, while the Gain controls increase the signal level for more tube color.

Note: Like the original hardware, values on the control labels may not match actual measured values.

UA 610-A

Input Gain

The two-position LOW/HI rotary switch exposes the little-known internal gain jumpers that are on the circuit boards inside the vintage modules. Setting the switch to the HI position adds approximately 8 dB of gain at the tube input stage and also

changes the distortion characteristics. This is a digital-only control unavailable on the original hardware module.

Important: Use caution when switching 610-A Gain from LOW to HI, as signal output levels could jump dramatically.

Input Pad

Additional attenuation for the Mic input is available via the two-position Pad switch. Setting the switch to the "-20" (up) position attenuates

the Mic signal at the tube input stage by -20 dB. In the down position, no attenuation is applied.

Note: The 610-A Input Pad is not available for line input.

UA 610-B

Input Gain

The 5-position rotary Gain switch changes the level at the tube input stage. The control attenuates the input signal by –10 or –5 dB, or adds +5 or +10 dB of gain. In the center "O" position, neither gain nor attenuation is applied.

Input Pad

Additional attenuation for the Mic input is available via the two-position Pad switch. Setting the switch to the "-15" (up) position attenuates the Mic signal at the tube input stage by -15 dB. In the down position, no attenuation is applied.

-15 () PAD

Note: The 610-B Input Pad is not available for line input.

Output Level Controls

Level

Level (aka "the big knob") is used to control the gain of the tube output stage of the preamp. Higher values add more coloration.

The amount of available gain using this control is approximately 61 dB for both plug-in models.

Output

signal. The range is from –∞ dB (off) to +12 dB. This control, which does not exist on the original

hardware, facilitates the ability to maximize color of

Output adjusts the signal level at the output of the plug-in without effecting the sonic character of the

the overall signal. For example, Gain and Level can be cranked for more distortion, while lowering Output to normalize levels. This is similar to having the line output of a 610 plugged into a console and using the console fader to pad the output of the 610.

Tip: Click the "0" label text above the control to return Output to 0 dB.

The UA 610 preamps feature high and low frequency boost/cut shelving filters with stepped gain controls. The equalizers utilize a feedback-style design which effects the distortion characteristics of the output stage.

UA 610-A

The low frequency ("L.F.") shelf EQ has a fixed cutoff frequency of 100 Hz.

Lo EQ Gain

This rotary switch determines the amount of boost or cut applied to the low frequency signal. Fixed values of ± 6 dB or 0 dB can be selected. When set to 0 dB, the filter is inactive.

📲 UA 610-B

The low frequency ("LO") shelf EQ has a selectable cutoff frequency which can be cut or boosted by various amounts.

Lo EQ Frequency

This switch determines the cutoff frequency (70, 100, or 200 Hz) of the low shelf EQ. This switch has no effect if the Lo EQ Gain value is zero.

Note: Like the hardware, low frequency values are not consecutively ordered.

Lo EQ Gain

This rotary switch determines the amount of boost or cut applied to the low frequency signal. Fixed values of plus or minus 9, 6, 4.5, 3, or 1.5 dB can be selected. When set to 0 dB, the filter is inactive.

High EQ

UA 610-A

The high frequency ("H.F.") shelf EQ has a fixed cutoff frequency of 10 kHz.

Hi EQ Gain

This rotary switch determines the amount of boost or cut applied to the high frequency signal. Fixed values of -6, 0, +3, or +6 dB can be selected. When set to 0 dB, the filter is inactive.

UA 610-B

The high frequency ("HI") shelf EQ has a selectable cutoff frequency which can be cut or boosted by various amounts.

Hi EQ Frequency

This switch determines the cutoff frequency (4.5 kHz, 7 kHz, or 10 kHz) of the high shelf EQ. This switch has no effect if the Hi EQ Gain value is zero.

Note: Like the hardware, high frequency values are not consecutively ordered.

Hi EQ Gain

This rotary switch determines the amount of boost or cut applied to the high frequency signal. Fixed values of plus or minus 9, 6, 4.5, 3, or 1.5 dB can be selected. When set to 0 dB, the filter is inactive.

Polarity

This switch inverts the polarity ("phase") of the signal. The signal 0 polarity is inverted when the switch is in the up position. Polarity is normal when the switch is in the down position. Polarity inver-

sion can help reduce phase cancellations when more than one microphone is used to record a single source.

When either plug-in is used in an INPUT insert within Apollo's Console application, software and hardware control of polarity is mirrored. Polarity can be inverted within the plug-in interface or by using Apollo's polarity button.

Power

Power is the plug-in bypass control. When (0) OFF set to OFF, emulation processing is disabled and DSP usage is reduced (if DSP LoadLock is inactive).

Power is useful for comparing the processed settings to the original signal.

610 History

Creating an original 610 desk meant buying the individual modules and building the console from scratch, as no complete consoles were ever sold commercially. However, Bill Putnam himself built a few full-fledged desks for his own studios, complete with fabricated frame, power supply, metering, and buss/effects routing options.

Although very few desks were built from 610 modules, their contribution to the history of recorded music is enormous. Ray Charles, Frank Sinatra and The Beach Boys were a few artists captured with the 610 at United/Western as part of landmark recordings such as "Sounds in Country and Western Music," "Strangers In The Night," and "Pet Sounds," respectively.

One of these 610 desks is the famous Wally Heider "Green Board." This extremely well-built example was originally fabricated by Frank DeMedio for Wally Heider's Remote Recording Service in the early '60s. Wally originally handled many of the live recording dates booked by Putnam. This console recorded and mixed some of the greatest performances of the era, from many live shows with the "Rat Pack," to recording the very last concert under the baton of Igor Stravinsky in Los Angeles.

With the Wally Heider Green Board alone, the list of records using the 610 is staggering. Here are but a few notable acts recorded with the Green Board: Duke Ellington, Elvis Presley, Johnny Cash at Folsom Prison, Fats Domino, Little Richard, Cream, The Beach Boys, The Doors, Janis Joplin with Big Brother & The Holding Company, The Who, The Grateful Dead, The Steve Miller Band, Moby Grape, The Byrds, Jefferson Airplane, Booker T. & the M.G.s, Otis Redding, Eric Burdon and The Animals, Simon and Garfunkel, and The Jimi Hendrix Experience (live at the Monterey Pop Festival, where he first set his guitar on fire!).

In the early '70s, long before this one-of-a-kind desk's historical significance could be anticipated, Neil Young bought the 12-channel board from Wally Heider. Young immediately moved it to his Broken Arrow Ranch. He installed the desk in his barn, which he used as a recording studio, and employed it to record his seminal record "Harvest" and may other classic albums. The Green Board remains at Broken Arrow Ranch, and is still in use today.

The original Wally Heider "Green Board" console containing 12 vintage UA 610-A preamplifier modules

The Universal Audio 2-610 Dual Channel Tube Preamplifier

CHAPTER 57 UAD Delay Compensation

Latency & Delay Compensation

When UAD Powered Plug-Ins are used, audio data to be processed by a UAD plug-in is sent by the host application to the UAD device. The audio is then processed by the UAD device and sent back to the host application. This back-and-forth shuffling of audio data is called "buffering" and it produces a latency (delay) in the audio signal being processed.

Latency is inherent in digital audio systems and it can be detected in certain situations. Latency time in a DAW is usually determined by the sample rate and audio I/O interface hardware buffer size settings.

If this latency is not compensated, the processed audio will not be perfectly aligned (synchronized) with unprocessed audio. Fortunately, modern audio plug-in host applications automatically compensate for this latency by simply enabling the delay compensation function in the preference settings. Most hosts provide full plug-in delay compensation throughout the entire signal path, including inserts, sends, groups/buses, and outputs

UAD latency and plug-in delay compensation is managed automatically by all modern DAWs using automatic plug-in delay compensation. Additionally, latency can be reduced to undetectable levels in UAD-2 PCIe cards and UAD-2 Satellite Thunderbolt by bypassing host buffering altogether (see "LiveTrack Mode" in the UAD System Manual).

Note: Delay compensation is fully automatic and requires no user intervention when UAD Powered Plug-Ins are used in hosts that support latency delay compensation.

Realtime UAD Processing with Apollo With Universal Audio's Apollo lineup of high-resolution audio interfaces, there is no buffering latency on input because the plug-in processing occurs on input within the interface itself (the data does not need to be shuttled to the DAW and back). **Host Application** Settings For optimum results, the delay compensation feature should be enabled in the host application, providing automatic compensation when UAD plug-ins are used. This option is usually found in the audio or plug-in preference settings window. The specific location of the setting for this option can be found in the host DAW documentation.

Latency compensation has various names depending on the host. It's usually referred to as "Automatic Delay Compensation" (ADC), "Plug-In Delay Compensation" (PDC) or a similar related name.

Upsampled Plug-Ins

Some UAD plug-ins use an internal sample rate of 192 kHz to achieve sonic design goals. This upsampling results in a slightly larger latency than other UAD plug-ins (typcially 0 – 300 samples, depending on the plug-in and sample rate). Therefore, they require more compensation to remain perfectly synchronized with other tracks.

Note: Compensating upsampled UAD plug-ins is performed automatically by the host application when latency compensation is enabled in the host.

Upsampled Compensation Notes

- Compensating for upsampled UAD plug-ins is not required when these plugins are used for program material on the output bus, where latency is not a consideration (because the entire mix is delayed by the same amount).
- The latency in Table 35 on page 564 is also produced when LiveTrack mode is used with upsampled plug-ins.
- Upsampled plug-in latency cannot be displayed in the "Plug-In Latency" section within the UAD Meter & Control Panel application due to technical limitations.
- The Precision Multiband and Ampex ATR-102 plug-ins have a significantly larger latency than other upsampled plug-ins because of their complex algorithms. Because manually compensating for these plug-ins in hosts that don't support full plug-in delay compensation can be complicated, to avoid timing errors in these hosts we generally recommend using these plug-ins only on outputs, so no manual compensation is required.

Note: Use the Precision Multiband and Ampex ATR-102 only on outputs (as their design was intended), or only in hosts that have full plug-in delay compensation.

Upsampling Values Table

Table 35 lists the additional latency produced by upsampled UAD plug-ins.

	Sample	e Rate (kl	Hz)

Table 35. Upsampled UAD plug-ins with additional latencies

*Note The EMT 250 and Lexicon 224 anti-aliasing filters for their A/D and D/A conversion are not linear-phase filters; therefore the emulations do not have a latency that is the same at all frequencies. Thus, we cannot report to the delay compensation engines a delay that is correct for all frequencies. The reported values are good at low frequencies, but become off at high frequencies.

For example, when the plug-in is in Delay program mode and set with zero delay time and predelay values, the plug-in output will not be completely cancelled when mixing with flipped phase against an unprocessed track; high frequencies will leak through. However, the latency through the dry side of the wet/dry mix, and the latency when the plugin is bypassed via the EMT 250 Power switch, do not have this issue and will be fully compensated by the DAW.

Live Processing (without Apollo)

The previous discussions of delay compensation applies primarily to playback and mixing of existing tracks on non-Apollo UAD-2 devices. During recording (tracking), the primary concern usually centers around getting the absolute lowest possible latency out of your hardware and software combination. The lower the latency is, the closer you can get to a realtime, "ears match the fingers" performance situation in the digital environment where some latency is unavoidable.

Realtime latency is displayed in the System Information panel within the UAD Meter & Control Panel application.

Live processing latency is determined by the sample rate and the audio interface I/O buffer size setting. Higher sample rates and lower buffer sizes produce lower latencies.

UAD-2 PCIe LiveTrack Mode UAD-2 PCIe cards and UAD-2 Satellite Thunderbolt use an advanced buffering architecture that delivers no additional latency when tracking by using LiveTrack Mode. See "LiveTrack Mode" in the UAD System Manual for details.
